Abstract

Background

Trefoil factor family cytokines (TFF1-3) have documented reparative and immunoregulatory effects on mucosal epithelial cells that include: blocking apoptosis, directed cell migration, and regulation of proinflammatory cytokine production. TFF1 and TFF3 have been shown to undergo altered expression within sinonasal tissues of patients with various forms of chronic rhinosinusitis including those with or wthout polyp associated disease, but the cellular source(s) of TFF members in CRS remains unclear. To further explore the role of TFF3 in inflammatory sinonasal disease, we sought to determine its expression pattern in immune and non-immune cell types in CRS disease.

Methods

Polyp and inferior turbinate tissues were isolated from patients undergoing surgical resection for treatment of CRS. Tissue homogenates and single cell suspensions were subjected to enzyme linked immunosorbent assay (ELISA) and single-cell RNA sequencing. Air liquid interface cultures of sinonasal epithelia were subjected to immunofluorescence (IF) microscopy. Interleukin 25, TFF2 and TFF3 protein levels were compared to sinonasal outcome test scores (SNOT-22) to determine whether levels associated with post-operative outcomes.

Results

TFF3 was broadly expressed in goblet cells, ciliated cells, Tuft cells and T lymphocytes. TFF3 protein levels positively associated with IL-25 in CRSwNP patients. Lastly, TFF3 protein levels positively associated with clinical improvement post-surgery.

Conclusions

TFF3 is broadly expressed within multiple epithelial and immune cell lineages in patients with CRSwNP. Protein levels of TFF3 correlate with IL-25 and clinical signs of disease, however TFF3 levels associate

Corresponding Author: Noam A. Cohen M.D. Ph.D

with clinical improvement following surgical intervention indicating a potential beneficial role for this

reparative cytokine in CRS patients.

Introduction

Chronic rhinosinusitis (CRS) is a complex upper airway inflammatory disease that affects 16% of the U.S. population¹. Among CRS patients, some present with a neutrophilic disease dominated by Type 1 cytokines, whereas some individuals develop nasal polyps (CRSwNP) exhibit upper respiratory pathology dominated by Type 2 cytokines (e.g. interleukins 4, 5, 13, 25 and 33) eosinophils, mast cells, basophils and group 2 innate lymphoid cells (ILC2)². While the mechanisms responsible for initiation of CRSwNP disease remain obscure, recent work has shown that in these patients, the major source of the Type 2 polarizing cytokine IL-25 is the Tuft cell/Solitary Chemosensory Cell (SCC)³. Tuft cells are a rare epithelial cell lineage that utilize taste receptor genes as sensors to the external microenvironment, where they serve a host protective role by augmenting anti-microbial activity of neighboring cells⁴. Tuft cells are also a major source of immunostimulatory mediators such as cysteinyl leukotrienes and IL-25⁵. Tuft cell derived IL-25 promotes ILC2 expansion and this circuit is enriched in nasal polyp tissues from CRSwNP patients⁶. However, the notion that pathological Type 2 diseases of the airway including allergic asthma and CRSwNP are potentially maladaptive wound healing responses has not been widely considered.

Among known pathways of tissue repair, the Trefoil factor family of reparative cytokines (TFF1, TFF2 and TFF3) are small 6-12kDa cloverleaf-shaped molecules secreted mostly from goblet cells at mucosal barrier surfaces⁷. These cytokines promote resolution of tissue injury through the following: resistance to apoptosis, regulation of cell adhesion, suppression of pro-inflammatory cytokines, and directing cellular migration across denuded basement membrane through a process termed restitution⁸. In the context of CRS, increased gene expression levels for TFF1 and 3 in the sinonasal mucosa has been reported for the Type 1 associated CRSsNP subtype⁹. Moreover, increased TFF3 with concomittant decreased TFF1 gene expression levels in the sinonasal mucosa has been reported for the Type 2 associated CRSwNP subtype¹⁰. TFFs are expressed in healthy and diseased tissue in human and mouse models and correlate with disease severity in asthma and COPD^{11, 12}. In mice, it was shown that TFF2

Corresponding Author: Noam A. Cohen M.D. Ph.D

was necessary for the production of IL-33, which aided the initiation of Type 2 inflammation during allergen exposure and pathogen infection of the lower airways¹³. In addition to its immunoregulatory role(s), TFF3 also has been shown to promote differentiation of beta-tubulin expressing ciliated cells through a mechanism that relied upon epidermal growth factor receptor activation¹⁴. Despite these insights, there is still a poor understanding of whether TFF members are important for immunoregulation, healing post-surgical intervention, and/or developmental cell lineage sources in CRS patients.

In this study, we used single cell RNA sequencing (sc-RNAseq) to map the cellular expression pattern for TFF genes in CRSwNP patient tissue and determine whether Trefoil protein levels correlated with disease outcome. TFF3 was predominantly expressed in a surprisingly wide array of epithelial and immune cell lineages. Immunostaining of nasal polyp tissues revealed TFF3 was expressed in cells with Tuft cell morphology, which was strikingly consistent with positive correlation between TFF3 and IL-25 levels in mucosal tissues of CRS patients. Combined with the positive association between TFF3 levels and improved clinical outcomes post-surgical intervention for polyp removal, this work indicates that TFF3 may be potentially an important biomarker indicating the extent of pathological Type 2 disease in th context of CRSwNP disease.

Methods

Patients and specimen collection

Patients with CRS were recruited from the Department of Otorhinolaryngology – Head and Neck Surgery, Division of Rhinology at the University of Pennsylvania with voluntary informed consent. Patients met the criteria for CRS as defined by the Academy of Otolaryngology—Head and Neck Surgery clinical practice guidelines for adult sinusitis¹⁵. Sinonasal tissue samples were obtained during routine endoscopic sinus surgery for CRS management after patients had previously failed adequate medical therapy. Patients with a diagnosis of cystic fibrosis, sarcoidosis, immunodeficiency and granulomatosis

Corresponding Author: Noam A. Cohen M.D. Ph.D

polyangiitis were excluded. This study was approved by the University of Pennsylvania Institutional Review Board.

Transcriptome Analysis

Polyp and inferior turbinate (IT) samples from two patients with CRS with nasal polyposis (CRSwNP) were rinsed 3 times with Dulbecco modified Eagle medium containing 100 U/mL penicillin (MilliporeSigma, Burlington, MA), 100 µg/mL streptomycin (MilliporeSigma), and 250 ng/mL amphotericin B (MilliporeSigma). Single cell dissociation was performed by incubating 1-2cm samples in Liberase disruption solution (MilliporeSigma). Digestion was stopped with 5mL of of DMEM+ 10% fetal bovine serum and the digest contents were filtered through a 40-micron cell strainer. The filtrate was centrifuged at 1,200 rpm for 5 minutes and the supernatant was discarded. The cells were resuspended in 5 mL of chilled 0.04% bovine serum albumin (BSA) in PBS and counted with a manual cytometer using trypan blue (Thermo Fisher Scientfic, Waltham, MA). Chilled 0.04% BSA in PBS was added to achieve a target cell concentration of 700-1200 cells/µl. Cell suspensions were loaded on a GemCode Single-Cell Instrument (10x Genomics, Pleasanton, CA) along with reverse transcription reagents, gel beads containing barcoded oligonucleotides and oil to generate single-cell Gel Beads in Emulsion. Using the GemCode Single-Cell 3' Gel Bead and Library kit (10x Genomics) an scRNAseq library was prepared. These sequencing libraries were loaded on an Illumina NextSeq500 (Illumina, San Diego, CA) and demultiplexing, barcode processing and single-cell 3' counting were performed using the Cell Ranger Single-Cell Software Suite (10x Genomics).

Tissue homogenization

Polyp and IT samples from 16 patients with CRSwNP and 12 patients with CRS without nasal polyposis (CRSsNP) were collected and rinsed as described above. Samples were finely minced in a solution of 1 mL of 1× PBS containing complete Mini Protease Cocktail Inhibitor (Roche, Indianapolis, IN) and homogenized on ice using a Dounce homogenizer. Homogenized samples were transferred to an

Corresponding Author: Noam A. Cohen M.D. Ph.D

Eppendorf tube, centrifuged at 14,000 rpm for 5 minutes and the supernatant was transferred to a fresh Eppendorf tube. Samples were stored at -20° C until assayed for TFF3, TFF2, IL-25 and total protein levels, as described below.

TFF2, TFF3, IL-25 ELISA and total protein quantification

Human TFF2, TFF3 and IL-25 ELISA (R&D Systems, Minneapolis, MN) was performed according to the manufacturer's instructions with samples of homogenized sinonasal tissue (at 1:5 and 1:15 dilutions). Total protein concentrations for homogenized tissue samples were determined using a bicinchoninic acid protein assay (Thermo Fisher Scientific) in microwell format according to the manufacturer's instructions and TFF2, TFF3, and IL-25 levels were normalized to total protein levels. Optical density was measured with a microplate reader at wavelengths of 450nm and 570nm for TFF3, TFF2, IL-25 and 562nm for total protein.

Chart Review

Demographic data, including age and gender, were collected along with disease characteristics (including prior surgeries, pre-and post-operative scores on the validated 22-item sino-nasal outcomes test (SNOT-22¹⁶ and comorbidities (including prior diagnoses of asthma and allergic rhinitis) (Table 1). Pre-operative SNOT-22 scores were collected 1-4 weeks prior to day of surgery. Post-operative SNOT-22 scores were collected 4-6 weeks after surgery. Delta SNOT-22 scores were calculated as the pre-operative SNOT-22 score minus the post-operative SNOT-22 score. Pre-operative radiographic computerized tomography (CT) scans of the sinuses were also reviewed and scored based on the Lund-Mackay (LM) staging system for CRS¹⁷.

Analyses

Data were analyzed using Microsoft Excel (Microsoft, Redmond, WA) and Prism (GraphPad Software, La Jolla, CA) software. Linear correlations between TFF3, TFF2, and IL-25 protein levels, and between

Corresponding Author: Noam A. Cohen M.D. Ph.D

TFF3 protein levels and SNOT-22 scores (baseline and delta) were assessed using the non-parametric Spearman's rank correlation test.

Single-cell RNA sequencing results were analyzed using the computational R toolkit Seurat¹⁸. We processed two scRNA-seq datasets (2 inferior turbinate and polyp samples were merged and filtered, n=14,013 cells) and created objects with molecular features which are detected in at least 3 cells; each cell had at least 200 molecular features. UMAP plots with single cells were colored by K-nearest neighbor (KNN) clusters and cell types using a ROC test¹⁹. The top 20 gene markers for each cluster were exported for cell annotation according to the public cell marked database²⁰.

Results

Among TFFs, TFF3 is selectively enriched in multiple cell populations during CRS disease

Given previous reports that TFF levels are elevated in CRS tissues⁹, we sought to interrogate the lineage identity of TFF expressing cells using single cell RNA-sequencing (scRNA-seq). To this end, we subjected a pool of tissues collected from inferior turbinate and polyp tissue for the generation of single cell suspensions. We prepared sequencing libraries from 15,423 single cells, which were loaded into the Illumina NextSeq 500 Sequencing System (Illumina, San Diego, CA) and processed using the 10x Genomics Software Suite. We explored our scRNA-seq dataset using the computational R toolkit Seurat¹⁸ to identify cell clusters and differential gene expression within these cell clusters at the transcript level. We identified 13 cell clusters which were annotated by cell type with the top 20 lineage-specific genes per cluster using the CellMarker public database²⁰ (Figure 1A). Comparison of cell clusters that showed positive expression for one or more member of the TFF family, we noted that TFF2 showed the most limited expression whereas TFF3 was most broadly expressed (Figure 1B-C). Combined analysis of both inferior turbinate and polyp tissue revealed that TFF1 was a predominant feature of the goblet cell cluster, whereas TFF3 was expressed in clusters identified as goblet cells, ciliated cells, basal cells, and SCC/Ionocytes (Figure 1D). Interestingly, we found overlapping expression between TFF3 and the SCC/tuft cell lineage specific genes *POU2F3* and *TRPM5* (Figure 1C). Consistent

Corresponding Author: Noam A. Cohen M.D. Ph.D

with our previous work, the scRNA-seq analysis reveals increased II25 mRNA expression in polyp tissue³ (Figure 1D). Unexpectedly, there was a moderate number of TFF3 expressing cells within the immune system as defined by CD45 (*PTPRC*) and CD11c (*ITGAX*) that are genes expressed in NK/T lymphocytes, monocytes/macrophages, mast cells/basophils and B cells/plasma cells (Figures 1A-C). Combined, these data show that TFF3 is the most predominant member among the TFF family and it is expressed broadly in mature and progenitor epithelial lineages and immune cell populations in patients with CRS disease.

TFF3 but not TFF2 correlates with IL-25 production in CRSwNP

Given the central role served by SCC/tuft cell lineages in producing IL-25 to promote Type 2 immunity²¹, we next sought to determine whether TFF3 protein levels in the mucosa of CRS patients correlated with IL-25 levels. Commercially available ELISA kits specific for TFF2, TFF3 and IL-25 were used to compare levels of these cytokines in homogenized tissues from CRSwNP) and non-polyp (CRSsNP) patients. These data were used to generate Spearman correlation coefficients from the linear association of IL-25 protein levels and TFF3 or TFF2 in CRSwNP (Figure 2A) and CRSsNP (Figure 2B). We find that IL-25 protein levels were significantly correlated with TFF3 protein levels in CRSwNP patient samples (Figure 2A: $r_s = 0.544$, p = 0.03). In contrast, there was no significant correlation between IL-25 protein levels and TFF2 protein levels in either CRSwNP (Figure 2A: $r_s = 0.094$, p = 0.72) nor CRSsNP (Figure 2B: $r_s = 0.010$, p = 0.97). We also did not find any significant correlation between IL-25 protein levels in CRSsNP (Figure 2B: $r_s = 0.010$, p = 0.97). We also did not find any significant correlation between IL-25 protein levels and TFF3 protein levels in CRSsNP (Figure 2B: $r_s = 0.055$, p = 0.86). Thus, these data suggest that TFF3 but not TFF2 is associated with IL-25 production in CRSwNP.

Next, TFF3-specific immunostaining was performed on air-liquid interface (ALI) cultures of a sinonasal epithelial cell cultures grown from a CRSwNP patients. Evaluation of these tissues using differential interference contrast imaging overlaid upon the fluorescence signal revealed punctate TFF3 staining in cells with apical microvilli and tuft-like cell morphology (Figures 2C-E). Collectively, these

Corresponding Author: Noam A. Cohen M.D. Ph.D

data reveal that TFF3 and IL-25 protein levels are closely correlated within the mucosal tissue of CRSwNP patients.

Impact of TFF3 on clinical markers of disease severity and post-operative tissue repair in CRS disease.

Lastly, we asked whether TFF3 correlated with clinical markers of disease severity and post surgical symptom resolution. The Sino-Nasal Outcome Test (SNOT-22) is a patient-reported outcome measure for patients with sinonasal disease with 22 questions designed to assess symptom severity²², and is often used to evaluate efficacy of therapeutic intervention²³. Therefore, we compiled baseline and post-operative (6 month) SNOT-22 scores and calculated the change from baseline to post-operative SNOT-22 scores (deltaSNOT-22) from All CRS patients (n=25), CRSwNP (n=13) and CRSsNP (n=12). We then determined Spearman correlation coefficients from the linear association of TFF3 and baseline SNOT-22 scores (Figures 3A-C) or the change in SNOT-22 scores following surgical intervention (deltaSNOT-22 scores) (Figures 3B, 3E) and 3) CRSsNP (Figures 3C, 3F). Data show that the association between TFF3 protein levels and baseline SNOT-22 scores (n = 25) was significant for all CRS patients samples (Figure 3A: $r_s = 0.386$, p = 0.05) and CRSwNP patient samples (Figure 3B: $r_s = 0.558$, p = 0.05).

Further, when we interrogated the association between TFF3 protein levels and deltaSNOT-22 scores, there was only a significant correlation in CRSwNP patient samples (Figure 3E: $r_s = 0.621$, p = 0.02). There was no significant correlation between TFF3 protein levels and baseline SNOT-22 scores in CRSsNP samples (Figure 3C: $r_s = 0.077$, p = 0.81). Also, there was no significant association between TFF3 and deltaSNOT-22 scores in all CRS patient samples (Figure 3D: $r_s = 0.290$; p = 0.17) or CRSsNP patient samples (Figure 3F: $r_s = 0.097$; p = 0.78). We found no association between TFF3 protein levels and LM score overall or for any sub-group (data not shown). Taken together, these data show that TFF3 correlates with IL-25 production in CRSwNP (Figure 2A) as well as quality of life improvement following sinus surgery (Figure 3E).

Discussion

CRS is a complex and multi-factorial disease that encompasses a spectrum of immunological phenotypes ranging from Type 1/17 associated neutrophilic inflammation to a Type 2 associated eosinophil dominated response². Moreover, the pathology that accompanies Type 1/17 associated CRS is fibrosis, basement membrane thickening and goblet cell hyperplasia, whereas patients with Type 2 associated CRS develop nasal polyp disease²⁴. The underlying causes for CRS remain largely unknown irrespective of the disease subgroup, but prevailing theory posits that chronic defects in mucociliary clearance and/or epithelial repair mechanisms are responsible. This study investigated whether reparative molecules in the Trefoil factor family associate with Type 2 cytokines produced in CRSwNP patients and/or clinical outcomes following surgical intervention. Results from sc-RNAseq analysis show TFF3 was the predominant trefoil factor with a broad expression pattern that included multiple epithelial lineages and immune cells. Moreover, TFF3 protein levels within sinonasal mucosa of CRSwNP patients positively associated with the Type 2 polarizing cytokine IL-25 and greater disease burden as assessed by the SNOT-22 but also correlated with greater improvement following surgery. Taken together, this study warrants further investigation of the underlying mechanistic role(s) served by TFF3 in the pathogenesis of CRS.

Previous work using immunostaining approaches demonstrated that TFF1 and TFF3 are associated with allergic rhinitis and CRSsNP, whereas TFF2 was largely undetectable ^{9, 25}. In addition, measuring TFF1 and TFF3 mRNA levels in the sinonasal mucosa of CRSwNP patients revealed a significant upregulation of TFF3 gene expression concomittant with downregulation of TFF1 gene expression¹⁰. TFF1 and TFF3 are known products of goblet cells in both healthy and inflamed sinonasal tissues, TFF3 was also produced by ciliated epithelial cells, and submucosal glandular cells ^{25, 26}. While our results are consistent with these conclusions, our sc-RNAseq data additionally show that CRSwNP patients have *TFF3* expression in immune cells (NK/T lymphocytes), basal cells, and SCC/tuft cells. This latter finding is particularly significant because SCC/Tuft cells are major producers of IL-25 in CRSwNP patients and this circuit positively associated with ILC2 expansion⁶. Furthermore, basal cells are the

12

Corresponding Author: Noam A. Cohen M.D. Ph.D

progenitor population that gives rise to SCC/Tuft cells in the lower airway following severe influenza injury²⁷. TFF3 immunostaining on air liquid interface cultures of sinonasal epithelium from CRSwNP patients revealed a pyramidal morphology consistent with the distinctive nature of the SCC/Tuft population. Further investigation is certainly warranted to understand the significance of this unexpected TFF3 expression within SCC/Tuft cells and potentially pathogenic lymphocyte subsets.

TFF3 has dynamic effects upon epithelial cells that underlie its diverse roles in wound healing. TFF3 promoted differentiation of ciliated epithelial cells, making it possible that TFF3 may aid in the differentiation of IL-25-producing SCC/Tuft cells from basal cell progenitors in the sinonasal mucosa. Moreover, TFF3 has been shown to inhibit apoptosis and promote cellular proliferation, therefore, it may be possible TFF3 works through autocrine or paracrine mechanisms to sustain SCC/Tuft cell derived IL-25. TFF3 blocks epithelial cell apoptosis through a mechanism that requires interactions with the type 1 membrane receptor LINGO2²⁸. While the biological role for LINGO2 is largely unknown, LINGO2 polymorphisms are significantly associated with allergic asthma in humans²⁹. Nonetheless, whether a TFF3-LINGO2 interaction works directly or indirectly upon SCC/Tuft cells to promote their expansion, survival and IL-25 production in CRS remains entirely unknown. Given such complexity and the enigmatic nature of CRS in general, a genetically tractable experimental model system will be required to thoroughly investigate this hypothesis.

Having found that TFF3 correlates with IL-25 production in CRSwNP patients, we then asked whether TFF3 also correlated with clinical indicators of disease as defined by SNOT 22 scores. Indeed, there was a positive association between TFF3 and increased SNOT 22. These data could either reflect a inductive role for TFF3 in CRSwNP pathophysiology or that increased TFF3 is an endogenous response intended to resolve areas of damaged tissue, but somehow in this context it is insufficient to do so. Thus, while it remains unclear whether TFF3 is serving a protective or pathogenic role, TFF3 levels in general may be an indicator for inflammation among all CRS endotypes but perhaps more significantly in

Corresponding Author: Noam A. Cohen M.D. Ph.D

CRSwNP disease. Overall, our data imply that TFF3 levels in sinonasal tissue biopsies could potentially serve as a biomarker for active CRS and/or good clinical outcomes following nasal polyp resection.

In conclusion, this study demonstrates that the reparative cytokine TFF3 is expressed at the mRNA level within multiple immune and non-immune cell types of patients with CRSwNP disease. Protein levels of TFF3 correlate with IL-25 and clinical signs of disease, which indicates that TFF3 deserves further investigation into its mechanism of action in this debilitating chronic inflammatory disease. A greater understanding of TFF3 in this context also has the potential to reveal important information about the role(s) served by SCC/Tuft cells in human disease.

Conclusions

TFF3 is emerging as a commonly dysregulated reparative cytokine in human diseases that involve mucosal barrier disruption including allergic asthma, COPD and multiple subtypes of CRS. This study demonstrates that TFF3 expression is broadly upregulated in inflamed sinonasal tissue and correlates with IL-25 and clinical markers of disease suggesting that nasal polyp formation is associated with dysregulated epithelial repair pathways. Understanding the mechanisms in which TFF3 signals in the epithelium through receptor mediated pathways is critical for pursuit of TFF3 proteins as clinically relevant therapeutic targets in humans given the promise shown in animal models^{30, 31}.

Tables

	CRSwNP	CRSsNP
N	16	12
Age (years)*	51.4 ± 12.5 (35-73)	53.8 ± 17.1 (25-75)
Gender (Male/Female)	(9/7)	(5/7)
AERD	3 (18.8%)	0
Allergic Rhinitis	15 (93.8%)	0
Asthma	8 (50%)	3 (25%)

Table 1. Characteristics of the patients enrolled in the study.

N, number of patients; CRSwNP, chronic rhinosinusitis with nasal polyposis; CRSsNP, chronic rhinosinusitis without nasal polyposis; AERD, aspirin-exacerbated respiratory disease, also known as Samter's Triad. *Data presented as mean ± SD (range).

Figures

Figure 1. Among Trefoil Proteins, TFF3 is selectively enriched in multiple cells populations during CRS disease. Single-cell RNA sequencing analysis for target genes (e.g., *TFF3*) using the dimension reduction method Uniform Manifold Approximation and Projection (UMAP) from two CRSwNP patient samples. **A.** UMAP plot displaying single cells clustered by KNN clusters and cell types. **B.** Heatmap displaying gene expression across cell clusters defined in (**A**). **C**. Feature plots show expression of *TFF2*, *TFF3*, *IL25* and other lineage-defining genes across cell clusters. **D.** Dot plot showing expression of *TFF1*, *TFF2*, *TFF3* and *IL25* in Solitary Chemosensory Cells (SCCs), Ciliated Cells, and Goblet Cells from Inferior Turbinate and Polyp tissue. *TFF1*, Trefoil factor 1; *TFF2*, Trefoil factor 2; *TFF3*, Trefoil factor 3; *IL25*, Interleukin 25; *POU2F3*, POU class 2 homeobox 3; *TRPM5*, Transient receptor potential cation channel subfamily M; *PTPRC*, Protein tyrosine phosphatase receptor type C; *ITGAX*, Integrin subunit alpha X.

Figure 2. TFF3 but not TFF2 correlates with IL-25 in CRSwNP. A. Spearman correlation between protein levels of IL-25 and TFF3 or TFF2 in 16 CRSwNP patient samples measured by ELISA. **B.** Spearman correlation between protein levels of IL-25 and TFF3 or TFF2 in 12 CRSsNP patient samples measured by ELISA. **C.** Differential Interference Contrast (DIC) Imaging of Air-Liquid Interface from sinonasal epithelial cell cultures grown from a CRSwNP patients demonstrating TFF3+ epithelial cells. **D.** Immunofluorescence (IF) Imaging of sinonasal epithelial cell cultures grown from a CRSwNP patients grown from CRSwNP patients demonstrating TFF3 expression in epithelial cells with distinctive SCC/tuft cell-like morphology, indicated by arrowheads. **E.** IF maginification of CRSwNP human nasal epithelium samples.

Figure 3. Impact of TFF3 on clinical markers of disease severity and post-operative tissue repair in CRS disease. We performed spearman correlation analyses between Baseline SNOT-22 scores, a clinical marker of disease severity, and TFF3 protein levels in All CRS (**A**), CRSwNP (**B**), and CRSsNP (**C**). Next, we performed spearman correlation analyses between deltaSNOT-22 scores, a metric of the change
