ABSTRACT

Background: Eggs are nutrient dense and rich source of quality protein and their consumption could significantly reduce incidence of chronic and infectious diseases especially in the elderly. This study determined egg consumption and factors that influence consumption among the elderly in Tamale metropolis.

Methods: Analytical cross-sectional study was conducted among 387 older adults 60 years and above. Data on egg consumption, nutritional knowledge and awareness of health implications of egg intake were collected using structured questionnaire. Relationships between egg consumption, nutritional knowledge and awareness of health effects of egg consumption were determined in bivariate and multivariate analysis.

Results: Respondents without awareness that egg intake increases risk of diseases were 10 times more likely to eat eggs compared to those who had awareness [Adjusted Odds Ratio 10.24; 95% Confidence Interval (CI) 4.20 – 25.00; $p = 0.001$]. Respondents with awareness that egg consumption was bad for health were less likely to consume eggs compared to those who thought egg intake was good for health [AOR 0.02; 95 % CI, 0.01 – 0.05, $p < 0.001$].

Conclusion: Egg consumption was low among the study population and was affected by health concerns: awareness that egg consumption was not good for health and exposes them to the risk of certain diseases

Key words: Aged, egg consumption, Tamale

INTRODUCTION

Background

The proportion of persons aged 60 years and above in the Ghanaian population in 2000 was 7.2 % and is expected to reach 14.1 % by 2050 ¹. The older adults are nutritionally vulnerable and exposed to increased risk of chronic diseases, disability and death. A number of factors (i.e., physiological changes, economic and social factors) significantly influence dietary intake in older adults ². Inadequate nutrition, particularly reduced protein intake in older adults, is a significant contributor to sarcopenia, a predictor of early mortality and morbidities ^{3,4}. Increased protein intake could be a useful strategy to promote good health and rapid recovery from illness in the elderly and reduce the incidence of sarcopenia among aging people ^{3,5,6}.

Eggs provide rich natural source of high quality protein and a number of vital nutrients including vitamins A, B12, B5, and D, folate, choline, phosphorus, selenium, and good amounts of vitamins E, K, and B6, calcium and zinc ^{7,8}. Egg has the highest value for protein digestibility (97 %) compared to all other sources of good quality protein ⁹ making it uniquely important for muscle protein synthesis than any other dietary protein ⁵. In relation to other sources of protein, eggs are inexpensive, easy to cook, chew and swallow and have long shelf life ³ and could be important source of protein for old people should it form integral part of their diets. Despite being nutritionally dense, eggs have been reported to increase the risk of certain lifestyles diseases by increasing blood cholesterol level ^{10,11} but this finding has not been supported by current research ¹².

A study conducted in the United Kingdom suggested that older British adults consume 16 to 17 eggs a month with a reported protein intake of 1.24 ± 0.42 g/kg body weight per day. In Ghana, there is hardly any scientific data on egg consumption for that matter protein intake by older adults. Such data could be necessary for development of

effective national strategy to promote good quality protein intake among older adults and reduce age-related complications for improved health. This study therefore sought to determine the prevalence of egg consumption and its associated factors among older adults in Tamale Metropolis, Ghana.

Methods

Study Area

This study was conducted in Tamale Metropolis of Northern Region of Ghana. The Metropolis has estimated land size of 646.90 km² and a total population of 233,252. It is boarded by Sagnarigu district to the west and north, Mion district to the east, East Gonja district to the south and Central Gonja to the south west ¹³. The persons aged 60 years and above constitute 5.1 % of the population of the metropolis ¹³. The metropolis has one rainy season in a year from May to October, and a long dry season characterized by dry harmattan winds from November to February.

Study design, population and sampling

A cross-sectional study was conducted between April and May, 2018 among respondents aged 60 years and above in ten selected urban and peri-urban communities: Sawaba, Gunayeli, Aboabo, Dungu-kukuo, Choggu, Bilpela, Nyohini, Kunyevilla, Fuo-yepala and Wombebe,

Sample size was determined using the formula $N = [Z^2 p (1-p)] / ME^2$ ¹⁴, where N = sample size, Z = confidence interval (CI) at 95 % = 1.96, p = assumed prevalence of egg consumption among older adults (50 %), q = 1-0.5 = 0.5, ME= margin of error (5% = 0.05). This yielded 384 so a sample size of 387 was used.

Systematic random sampling was used in selecting the participants of the study. Whenever a selected house had more than one eligible respondent, only one was selected using simple random sampling.

Inclusion and exclusion criteria

An older adult was eligible for interview if he or she was resident in a selected community, was able to answer questions and consented to be part of the study, or excluded if otherwise.

Data Collection

Data were collected in face-to-face interviews in homes using a pre-tested structured questionnaire. Data were collected on socio-demographic and economic characteristics of respondents (e.g., education, marital status, religion, income), and egg consumption (i.e., frequency of egg consumption, perception of disease risk associated with egg consumption). The questions on egg consumption were largely drawn from studies similar to ours^{15,16} and used without further statistical validation.

Quality Control

The questionnaire was pre-tested in two communities outside the selected ones and any ambiguous questions restructured. For example, questions that elicited implausible responses (i.e., responses that were not meaningful and/or related to possible responses) were deemed to be ambiguous. Such questions were restructured with the help of language experts to ensure they conveyed the right meanings. The data collectors were taken through the questionnaire for common understanding and administration. The administered questionnaires were checked on the field for completeness and consistency by supervisors at the end of each day before the teams left the communities.

Data Analysis

Data management and analysis were done using Statistical Package for Social Sciences (SPSS) (version 21) for windows. Frequencies and percentages were computed for categorical data. Associations between consumption of eggs (dependent variable) and associated factors (independent variables) were explored in bivariate and multivariate analyses. Bivariate analysis was done as first-line test using chi-square to identify possible predictors of egg consumption. Factors with significant associations at $P = 0.025^{17,18}$ were included in a logistic regression analysis to determine their independent effects. In the final model statistical significance was declared at $p < 0.05$.

Results

Socio-demographic characteristics of respondents

Majority (71.8 %) of the respondents were within 60-69 years age group, 86.8 % were Dagombas, and 98.7 % were Moslems. Majority (53.0 %) were males whilst 59.2 % and 52.2 % were self-employed and lived in rural areas of the metropolis respectively (Table 1). Majority, 76.2 % of the respondents, had no formal education and 79.8% were married.

Egg consumption knowledge of respondents

Results of the respondents' knowledge and perception on egg as a constituent of the diet are presented in Table 2. Most (81.7 %) of the respondents consumed eggs but the rest claimed they did not consume it because of certain traditional beliefs and practices. Whilst most (71.8 %) thought egg consumption was good for health, 18.1 % thought it exposed them to increased risk of certain lifestyle diseases for which reason 64.3 % of these people did not eat it. About 26 % of the respondents mentioned at least one non-communicable disease attributed to the consumption of eggs.

Egg consumption and its associated factors

Majority (70.0%) of the respondents ate 10 eggs a month. Majority (64.2 %) of the respondents kept domestic birds with 65.5 % of those who kept birds consuming eggs from their birds. While most of the respondents (49.4 %) were unable to quantify their daily expenditure on eggs, 41.8 % spent not more than one Ghana Cedis (GHS1.00) (GHS5.00 = USD 1) a day on it (Table 3). The factors reported to influence egg intake by the respondents were availability (38.0 %) and nutrient content of eggs or health concern (26.6 %). Majority (54.1 %) ate eggs occasionally and at most one egg at a time (58.5 %). Two weeks prior to the study, more than 90 % of the respondents went at least

a day without eating egg due to lack of money and this happened more than 6 times a week for the majority (53.6 %) of them.

*GHS5 = USD 1

Possible factors associated with egg consumption measured in this study were tested in bivariate analysis for statistical association. Education, monthly income, eggs being forbidden, perception that eggs are bad for health, perception that egg consumption increases risk of certain diseases and area of residence were significantly associated with egg consumption in bivariate analyses (Table 4).

*GHS5 = USD 1

Independent effects of these predictors were tested in logistic regression analysis for significance. Respondents who perceived that egg consumption was bad for health were less likely to consume it compared to those who did not have this perception [Adjusted Odds Ratio (AOR) 0.02; 95 % Confidence Interval (CI) 0.01 – 0.05; p < 0.001] (Table 5). Similarly, those without the perception that egg consumption increases the risk of certain diseases were 10 times more likely to consume it compared to those with this perception (AOR 10.24; 95% CI 4.20 – 25.00; p= 0.001).

Table 5: Determinants of egg consumption

Characteristic	Adjusted OR	95% Confidence Interval	P-value
Highest educational level			
No education	0.56	0.16-1.98	0.370

Discussion

This study sought to determine the prevalence of egg consumption and the factors that affect it in older adults in Tamale metropolis, Ghana. The findings of the study revealed that the prevalence of egg consumption in the older adults was low, and was mainly affected by the perception that egg consumption has adverse health effects and increases the risk of certain lifestyle diseases.

The study subjects consumed 10 eggs a month but we did not find any suitable studies on Ghanaian older adults for comparison. However, the prevalence of egg consumption measured compares favourably to an estimate of about 12 eggs a month reported for Ghanaians in 2017¹⁹. It was also consistent with consumption in South Africa where consumption per person per year was 150 eggs²⁰. Egg consumption was rather very low in many African countries. For instance in Zambia, Namibia and Botswana, consumption was 4, 8 and approximately 3 eggs per person per month respectively²⁰. Comparatively egg consumption in Africa was much lower than the reported consumption of 22 and 16-17 eggs a month among British adults 55 years and above, and 65 years and above respectively²¹. Though the proportion of the study participants who admitted consuming egg was high (81.7 %), consumption was mostly occasional and at those instances only one egg was eaten at a time.

From this study the main determinant of egg consumption among older adults in Tamale metropolis was health concern. The perceptions that egg consumption was not good for health and it exposes one to risk of certain diseases showed strong association with egg consumption. Individuals who had the perception that egg consumption had adverse health effects and could specifically increase the risk of certain lifestyle diseases were less likely to consume it. This fear was probably founded on earlier publications which associated high cholesterol containing foods to high blood cholesterol level and coronary heart disease ¹⁰. A prospective cohort study involving a large cohort of physicians in the United States strongly associated consumption of 7 or more eggs a week with greater risks of cardiovascular disease and death ¹¹. However, results from a meta-analysis of prospective cohort studies with large sample sizes and long durations of follow-up showed that an egg a day is safe and is not associated with an increased risk of cardiovascular disease or stroke ¹². Blood cholesterol level attributable to consumption of eggs presents no significant health risk than cholesterol derived from consumption of dietary saturated fatty acids ^{22,23}. Based on epidemiological evidence ²⁴ egg could be safely consumed by everybody including those diagnosed of cardiovascular disease or even type II diabetes in whom mortality was earlier strongly associated with egg consumption ¹¹. Though these findings eased restrictions on egg intake, there was still the fear among older adults in the current study who may be reluctant to change their eating habits to accommodate eggs in order to maintain low blood cholesterol ³. Even though area of residence, education, monthly income, and traditional practices and beliefs (forbid/taboo egg) strongly associated with egg consumption at bivariate level, they were not statistically significant at multivariate level.

Inadequate protein intake among older adults is a major contributor to sarcopenia and chronic diseases⁶. Poor dentition, inability to chew and dysphagia reduce food intake in older adults³ and contribute to inadequate protein intake^{25,26}. An increased intake of eggs could help reduce protein deficiency and associated health complications in older adults.

Conclusion

This study shows that the prevalence of egg consumption is low among older adults and is affected by the perception it increases the risk of certain diseases. Health promotion efforts aimed at promoting egg consumption in older adults should address health concerns.

LIMITATION

The study may suffer from recall bias since the egg consumption information was self-reported. Cross-sectional nature of the study prevented drawing of causal inference.

Our results are generalizable to older adult population in Tamale Metropolis.

DECLARATIONS

Ethics approval and consent to participate

The study protocol was approved by the Joint Ethical Review Committee of School of Medicine and Health Sciences and School of Allied Health Sciences, University for Development Studies, Tamale, Ghana (Protocol Number 01-2018). The study objectives were carefully explained to the participants who were also informed of privacy and data protection and written informed consent was obtained from each of them before recruitment onto the project. They were also informed of opportunity to withdraw from the study at any time if they so wished.

Consent for publication

Not applicable.

Availability of data and materials

Dataset relating to this article are available and could be obtained from the corresponding author upon reasonable request.

Competing interest

All authors declared they have no competing interest.

Funding

No funding was received for this study.

Acknowledgement

Authors thank the aged for their time in answering questions and also for making themselves available for measurements to be taken on them. We are thankful to Patience Boanyah and Salome Vida Lieru for helping in data collection.

Authors' contribution

HG designed the study and supervised data collection. AW analysed and interpreted data. EA and NS collected data from field and drafted initial manuscript. HG and AW reviewed the draft manuscript. All authors read and approved the final manuscript.
