Title of the paper:

A slow road from meat dominance to more sustainable diets: an analysis of purchase preferences

Keywords: grocery purchases, protein source, transition, sociodemographic, price

1 Abstract

2 Background: Achieving a sustainable and healthy diet requires increased replacement of red 3 meat with more sustainable foods. There is a call for novel methodologies to assess the 4 potential of different interventions and policies in enhancing the transition from the current to more sustainable choices. 5 **Objective:** We aimed to characterize consumer clusters with similar preferences in protein 6 7 sources, to compare the purchase prices of these foods, and to identify ongoing transitions 8 from one protein source to another. **Design:** Grocery purchase data with individual attributes on 29,437 consenting loyalty card 9 10 holders were analyzed over 2.3 year period. We designed a sequence analysis to group 11 participants to clusters with similar purchase preferences over the follow-up period and to estimate transition probabilities between preferences. We studied the determinants of 12 13 prevalent purchase profiles by ordinal logistic models. 14 **Results:** We identified six participant profiles with similar preferences in four protein sources: red meat, poultry, fish, and plant-based foods. Red meat dominated the purchase 15

16 preferences and showed the highest persistence over time. The majority (70%) of the

17 participants demonstrated somewhat mixed purchase profiles. A step-by-step transition from

18 red meat towards plant-based food preference seems most likely via poultry and fish. Overall,

19 low income was not a barrier to a more sustainable purchase profile, while price may deter the

20 purchase of fish. The most important resources in choosing more sustainable profiles were

education and stage of family life.

Conclusions: Societal incentives for sustainable food choices seem most crucial at transition
stages of life course and for the less educated. Here we also demonstrate that grocery
purchase data offer a valuable tool for monitoring the progressive transition towards a healthy
and sustainable food system.

2

26 Introduction

27 In the past century, a massive increase has occurred in the consumption of animal-based products, with a nearly doubled quantity of meat available for worldwide consumption 28 between 1961 and 2017 (1, 2). This global carnivore approach is neither nutritionally nor 29 environmentally sustainable (3, 4). There is an increasing endorsement of a new global 30 31 standard, a more plant-based diet, to achieve the 2030 United Nations sustainable goals and to relieve the burden of non-communicable diseases (5-9). One of the key claims of the 32 Planetary Health Diet was that by 2050 the global consumption of red meat will need to 33 reduce by more than 50% from the 2019 level (8). Achieving a sustainable diet would entail 34 35 increased replacement of red meat with sustainable fish and plant-based alternatives and a 36 simultaneous increase in fruit and vegetable intake (3, 6, 10, 11). However, both extremes – 37 strict animal product avoidance or high intake of red and processed meat – pose nutritional risks (3, 11-15). 38

39

Multiple and complex issues influence consumers' attitudes and behavior towards meat 40 41 consumption. Consumers should be able to distinguish between accurate information and 42 misinformation shaping their knowledge and attitudes (16). While making choices, consumers 43 may consider taste preferences, personal and family health, diet-related environmental issues, 44 animal welfare, religious or other ideologies, and cost (17-21). The weight of these issues varies by consumers' characteristics. Earlier studies show that meat eaters are more likely to 45 46 be men, middle-aged, less educated, and with a family (17,18, 22, 23).

47

There is a call for multiple indicators and novel methodologies to assess the potential of 48 49 different interventions, policies, and social media debates in enhancing the transition from the current to more sustainable dietary choices (24, 25). We used the extensive individualized 50

3

51 purchase data of the leading grocery retailing loyalty card program in Finland, with the *first* 52 *aim* of identifying and characterizing consumer clusters with similar preferences in protein sources. While red meat remains the most important meal component in most high-income 53 countries, transitions away from red meat as the main dish towards poultry, fish, and plant-54 based foods were examined. Our second aim was to compare the purchase prices of these 55 56 foods. To use the detailed data efficiently, we undertook a customized sequence analysis of 57 the preferred protein sources over time, enabling our *third aim*: the identification of ongoing transitions from one protein source to another. We emphasized the role of everyday, 58 educational, and economic resources and demographic factors in sustainable purchase 59 60 behavior and considered nutrition literacy and attitude as possible mediators. Given that 61 dietary behaviors are modifiable and most people consume these protein sources on a daily basis, our findings have critical public health and environmental implications. 62

4

63 Methods

64 *Study design*

Data were obtained from the S Group, which is the largest grocery retailer in Finland, with a 65 market share of 46% in 2018 (26). Members of the S Group's loyalty card program are 66 provided with a customer card to be used when making purchases, and loyalty card holders 67 are rewarded for their purchases by receiving a maximum 5% monetary reward that is 68 monthly refunded to them. Households' primary card holders across Finland were contacted 69 70 via email and invited to participate in the study, which involved consenting to the release of 71 their grocery purchase data for research purposes and voluntarily responding to an online 72 questionnaire that included questions on resources, attitudes, nutrition literacy, special diets, 73 and degree of loyalty to a retailer chain. The study was approved by the University of 74 Helsinki Ethical Review Board in the humanities and social and behavioral sciences 75 (Statement 21/2018). Each participant provided an informed consent electronically.

76

77 *Participants*

Initially, 47,066 loyalty card holders consented to release their 2.3-year grocery purchase data (Supplemental Figure 1). We did not have information on the number of valid email addresses or the proportion of emails reaching the card holders (e.g. bypassing trash email filters). Of the participants, 36,621 (78%) responded to the online questionnaire. For inclusion, we set a threshold of self-estimated degree of loyalty at ≥41%; the threshold value was based on an earlier observation that the relative shares of purchases of main food groups were similar among these participants (27). Thus, 29,437 participants were included in the analyses.

86 Background characteristics

5

87 Card holders' sex and age were obtained from the retailer's database. Information on 88 resources (family structure, education, household income) was collected via the questionnaire. The participants were classified into five family structure categories: single-adult households, 89 one adult and a child/children, two adults, two adults and a child/children, or other 90 (households with three or more adults and households with unknown family structure). 91 92 Participants reported their education on a four-point scale: primary school or less, upper 93 secondary school, lower level tertiary, or higher level tertiary. In addition, monthly gross household income was reported on a seven-point scale ranging from less than $1.500 \in$ to 94 9,000 € or more. Scaled monthly household income was then calculated as the mean income 95 96 in each of the categories divided by the square root of household size (OECD square root 97 scale) and classified into five categories: less than 1,000 €/month, 1,000–1,999 €/month, 2,000–2,999 €/month, 3,000–3,999 €/month, and 4,000 €/month or more. 98 99

100 Attitudes, nutrition literacy, and special diets

101 Attitudes and nutrition literacy were assessed with two questions measuring agreement with guidelines on fish, meat, and pulses given in the Nordic Nutrition Recommendations (28). 102 103 Respondents were asked to rate their opinion on the statements "To promote health, the 104 consumption of fish should be increased and that of red meat and processed meats limited" 105 (attitude) and "Recommended dietary changes include increasing the consumption of pulses" 106 (nutrition literacy). For both questions, a seven-point scale (from "1=fully disagree" to 107 "7=fully agree") was presented. We asked the respondents to indicate whether at least one 108 member of their household followed a diet with no red meat or a vegetarian or vegan diet. 109

110 *Grocery purchase variables*

6

111	The grocery purchase data used in this study covered the period from 1 September 2016 to 31
112	December 2018. Each purchase was linked to the card holder and associated with an item
113	description, time stamp, and quantity (i.e. weight, volume, or number of packages) and cost of
114	the item. The data consisted of 4,234 grocery product groups of which foods were re-grouped
115	by a professional nutritionist. We used the following food groups: red meat and processed
116	meat (R) including also processed white meat, poultry and poultry dishes (P), fish and
117	seafood (F), and plant-based foods (PB) including plant-protein products and vegetable
118	dishes, but excluding vegetables as such. The purchases were expressed in kilograms per
119	week.
120	
121	Statistical analysis
122	Grocery purchase data arise in a different way from traditional dietary data collection. Thus,
123	we analyzed the data in a way that condenses information in an effective and interpretable
124	way. Sequence analysis (29) is a technique for visualizing and learning from time-ordered
125	categorical data. Here, we designed a sequence analysis to group participants to clusters with
126	similar purchase preferences over the follow-up period and to estimated transition
127	probabilities between preferences.
128	

Differences in household size and in the degree of loyalty hinder comparisons between participants' absolute purchase volumes (27). Therefore, we first conducted a withinparticipant comparison of products. For each week of the follow-up, we computed the purchased volume of each food group. As food purchased in one week was not necessarily consumed that week, purchase volumes were defined as a backward moving average of two consecutive weeks. We labeled the participants' 'purchase preference' by the most purchased food group in that week, i.e. either as red meat, poultry, fish, or plant-based foods. Thus, each

7

participants' preference data could be expressed as a 123-letter long sequence, each letter
representing the purchase preference at one week. Missing purchase preferences, due to
absence of transactions in the two-week period, were coded as a preference of their own.

140 We defined the first week of September 2016 as the time origin and one week as the unit of 141 time in the sequence analysis. To estimate *prevalent purchase preferences*, participants were 142 clustered based on their temporal sequences of weekly preferences using the optimal 143 matching criteria, which is a way to measure (dis-)similarities between sequences of 144 categorical events, along with the hierarchical Ward clustering algorithm. Distances between 145 preferences were defined based on observed transition rates in the data. The choice of the 146 number of clusters was based on the height of consecutive steps in the dendrogram as well as 147 on their interpretability; after six clusters, the qualitative meanings of the clusters started to 148 overlap.

149

We investigated the determinants of prevalent purchase profiles by logistic (cumulative logit 150 link) models with cluster membership as an ordinal outcome. To achieve a meaningful 151 152 spectrum of sustainability of purchase profiles, clusters were ordered from the least 153 sustainable to the most sustainable profile. "Sustainability" was defined by the proportion of 154 purchased red meat in the profile. Thus, odds ratios >1 from this model indicated that the 155 factor studied tended to associate with more sustainable purchase profiles. Due to the large 156 sample size, we regarded statistical hypothesis tests as meaningless and focused on estimation of parameters characterizing the effect sizes. The proportional odds assumption was 157 158 investigated by the Bayesian Information Criteria comparing models with equal and unequal 159 parameters for each factor; no substantive deviations from the assumption were found. 160 Models were used to assess the role of demographic factors, resources, attitude, and nutrition

8

literacy in the sustainability of purchase profiles. We fitted an unadjusted model that included
factors one by one, a demographic and resource factors model, and a full model that also
included attitude and nutrition literacy variables.

164

We estimated the purchase prices of food groups by purchase profile; we computed the sums of the expenditure (€) on and the volume (kg) of food groups for each participant. Means and standard deviations were estimated from the distribution of their quotients such that each participant had the same weight in the calculation. The same was done for the totals over food groups and profiles. Purchase prices per food product were derived by a direct division of the total expenditure by the total volume across participants, as all products were not purchased by all participants.

173 To detect *changes in purchase preferences*, we estimated the transition probabilities of

174 switching from one preference (e.g. red meat and processed meat on week k) to another

175 preference (e.g. fish and seafood on week k+1). We focused on persistence of preferences

176 (i.e. no transition), transitions away from red meat and processed meat preference, and

177 transitions to plant-based food preference.

178 Data were analysed using the TraMineR package in R (30) and SAS version 9.4.

9

179

Results

180 Nearly one-third (29%) of participants representing their households lived with children, 56% 181 had at least a lower level tertiary education, and 31% had a modal scaled household income of 2000-2999 €/month (Table 1). For 9%, household income was lower than 1000 €/month. 182 183 Sixty-six percent of participants were women and 55% were at least 45 years old (Table 2). 184

185 Prevalent purchase preferences

186 Red meat and processed meat were by far the most common weekly purchase preference,

187 accounting for 63% of main protein sources, followed by poultry and poultry dishes (14%),

188 fish and seafood (11%), and plant-based foods (8%). Four percent of preferences were

189 missing.

190

191 Six clusters, or purchase profiles, were identified by the sequence analysis. The largest cluster 192 ("Red meat slightly mixed") contained 42% of participants. Their primary purchase 193 preference was red meat, but they also made regular purchases of poultry and fish, as seen 194 from their combined share of close to one-third of the purchase volume. The second largest 195 cluster ("Red meat", 25%) displayed a more dominant preference towards red meat, with 196 other alternatives together representing only one-quarter of the purchases. The third largest 197 cluster, still of notable size ("Mixed", 17%), displayed varying preferences. Proportions were 198 more equally spread across food groups, ranging from 14% to 44%. The three smallest 199 clusters had rather specific profiles: one ("Red meat and poultry", 9%) purchased red meat 200 and poultry in approximately equal amounts, but fish and plant-based products to a lesser 201 extent. Participants with the "Plant-based" profile (5%) mostly preferred plant-based foods. 202 Interestingly, poultry did not appear in the purchase profile nearly at all, and the proportion of 203 fish was small. The smallest cluster consisted of 2% of the participants; most of their

10

purchases were fish and seafood ("Fish"), followed by small but similar shares of red meat
and plant-based foods. Profiles are shown in the order from least sustainable (highest
proportion of red meat) to most sustainable (lowest proportion of red meat) (Figure 1).

208 Purchase profiles and background characteristics

209 Table 1 shows the distribution of purchase profiles by participants' resources. Among them,

210 differences across education levels were the most pronounced; higher education was

associated with a lesser likelihood of red meat dominance and with a greater prevalence of

212 mixed, red meat and poultry, plant-based, and fish profiles. Of those with primary school (or

less) education, 81% fell into clusters with red meat or red meat slightly mixed profiles.

214 Participants from households with the lowest and the highest income levels were less likely to

215 have a red meat dominant profile than those from other households. Plant-based profiles were

the most frequent among those with the lowest household income. Households with children

217 tended to prefer red meat more often than those without children.

218

A larger proportion of men had a red meat profile than women, and the opposite was observed for the plant-based profile (Table 2). The most striking difference between age groups was the profile distribution of the youngest age groups; only one in ten had the red meat dominant profile, and more than half had a mixed, red meat and poultry, or plant-based profile.

223

The frequency distributions of attitudes, nutrition literacy, and self-reported special diets by purchase profile are shown in Figure 2. Overall, 83% of participants agreed (response scoring ≥ 5) and 8% disagreed (response scoring ≤ 3) with the claim that the consumption of fish should be increased and that of red meat and processed meat decreased. The corresponding figures for an increase in consumption of pulses were 64% and 15%. Attitudes towards the

11

recommended changes in diet tended to be positive in all clusters, but mostly so for clusters
with mixed, plant-based food, or fish profiles. Participants with these profiles also reported
the highest rates of vegetarian diets and red meat avoidance (Figure 2).

232

233 An ordinal logistic model (Figure 3) considering the profiles ordered by their sustainability 234 indicated a pronounced trend across education levels; those with higher education tended to 235 have more sustainable purchase profiles. An inverse yet much weaker relation was observed 236 for household income; participants with the lowest household income tended to have more 237 sustainable profiles. The analysis also confirmed that households with children tended to have 238 less sustainable profiles than single or two-adult households. Attitude and nutrition literacy 239 seemed to act as intermediate factors for gender; women had somewhat more sustainable 240 profiles than men, and attitudes and nutrition literacy accounted for approximately half of this 241 difference. The model suggested a generation gradient, even after full adjustment. The 242 youngest age group stood out from the rest, showing a tendency towards more sustainable 243 profiles.

244

245 *Purchase prices*

246 Table 3 presents the mean prices of the purchased protein sources. The average price paid was the lowest for plant-based foods, followed by poultry and red meat, and the highest for fish. 247 There was considerable variation in purchase prices of products within all food groups. 248 249 Among the ten most purchased fish and seafood products, the most purchased products were 250 fresh rainbow trout and salmon, with prices ranging from 12.9 to 18.5 €/kg. The smallest 251 prices were paid for fish sticks: 5.3 €/kg. Of red meat and processed meat, the most purchased product was minced meat, with a purchase price range of 5.0-8.2 €/kg, whereas cold meat cuts 252 (11.3-12.7 €/kg) were bought with the highest prices. Traditional Finnish dishes of pea soup 253

12

(2.6 €/kg) and spinach pancakes (3.9 €/kg) were the most purchased plant-based foods. The
average purchase prices for the newly developed plant-based foods, such as pulled oats and
vegetable sausage, ranged from 12.2 to 18.3 €/kg, but the purchase volumes of these products
remained much smaller than those of traditional dishes. Participants with the red meat profile
tended to pay lower prices on average for most of the protein sources than other participants.
Those with the fish or mixed profile paid the highest prices.

260

261 Changes in purchase preferences

262 The estimated probabilities of preference persistence or transition from one week to another 263 are displayed in Table 4. Despite positive attitudes towards changes from red meat to fish and 264 increased consumption of pulses, the probability of persistence of red meat preference 265 remained steady and by far the strongest (82%). This was followed by persistence of plant-266 based food preference (53%). The persistence of all preferences and the departure and entry 267 probabilities for the two above-mentioned preferences over the follow-up period are displayed 268 in Figure 4. The probabilities were fairly stable over time; however, a slight increasing trend in the persistence of plant-based food preference was observed. Departure from red meat was 269 270 the most likely towards poultry, followed by fish and plant-based foods. The probability of 271 entry to plant-based food preference was the reverse; the most common entry was from fish 272 preference, followed by poultry and red meat preferences. Relative differences in the 273 transition probabilities were two- or even threefold across food groups.

13

Discussion 274

275 Our analyses of large Finnish grocery purchase data identified six purchase profiles with 276 different emphases on red meat, poultry, fish, and plant-based foods. Overall, red meat 277 dominated the purchases. Considerable variation existed in purchase prices within all food 278 groups, with the lowest average price paid for plant-based foods. Red meat and plant-based 279 preferences showed the highest persistence. Transitions from red meat were most likely to 280 shift towards other animal foods, favoring poultry over fish and fish over plant-based foods.

281 Our approach confirms recent findings from more traditional analyses (e.g. 31, 32); despite 282 the media hype and accumulating evidence supporting sustainable protein sources, red meat 283 preference and low regard for plant-based options are highlighted in purchase and 284 consumption profiles. Regardless of the slow rise in the proportion of vegan, vegetarian, and 285 red meat-free diets, the prevalence of different vegetarian diets remains modest in Finland 286 (33) and in other Western countries (22, 34). Also contrary to the impression given by public 287 debate, there was no evidence of polarization to opposite extremes (red meat or plant-based 288 foods) on the preference spectrum; the majority (70%) of participants demonstrated somewhat mixed purchase profiles. 289

290 Substituting red meat with fish, but not with poultry, may be associated with cardiovascular 291 health benefits (4), and there are sustainable fish choices available (35). Importantly, there 292 seems to be room for improvement in each purchase profile. Even those with plant-based food 293 profiles appeared to prefer red meat over fish. Future efforts need to be placed to accelerate 294 substituting meat with sustainable and affordable fish choices.

295 Currently, conceptual indicators and metrics for the economic and social domains of the 296 sustainable diet are the least developed (36). We particularly stressed these domains and observed that lower purchase prices tended to appear among less sustainable purchase 297

14

298 profiles. Within the food groups, however, the average price paid was the lowest for plant-299 based foods and almost triple that price for fish and seafood. Thus, more expensive products 300 are being purchased from the fish group or the variety of cheaper fish products is not as wide 301 or appealing. Differentials in the price of healthy and unhealthy foods and diets may 302 contribute to health inequalities (36). Based on our findings, price may act as a barrier to fish 303 purchases, but did not prevent purchase of plant-based foods. Participants with the lowest 304 household income had the most sustainable profiles, as was observed also in France (22). 305 Shifting from the current meat and protein-oriented diets to the current national dietary 306 guidelines has been projected to save more than one-third of the daily food expenditure 307 primarily due to replacement of expensive meat products with cheaper plant-based foods (10, 308 37). Previously, we demonstrated socio-demographic disparities in food choice motives, with 309 higher priority placed on familiarity and price in people with lower socio-economic position 310 and among men (38). Vainio et al. (39) found lower price to be an important food choice 311 motive among current beef consumers, in agreement with our observation that they tended to buy cheaper products. 312

It is noteworthy that the majority of participants agreed that the consumption of fish and 313 314 pulses should be increased and that of red meat and processed meat decreased. However, 315 attitudes and knowledge had not actualized in purchase behavior, as the proportions of fish 316 and pulses in the purchase profiles were relatively small. This is in line with a well-known 317 gap between stated attitudes or intentions and actual behavior (40). To increase sustainability 318 of consumers' food purchases, multiple actions that target both environmental (including 319 price) and more individual level behavioral determinants are needed. Importantly, of 320 interventions targeting conscious determinants of behavior, self-monitoring and individual 321 lifestyle counselling interventions have been most promising in reducing actual consumption 322 of meat (41).

15

We found that the most important resources in choosing more sustainable profiles were education and stage of family life. Similarly to previous studies (17, 18, 22, 23, 33), the red meat profile was common among less educated persons and men, but also among middle-aged participants with a family. The observed differences between the sexes could have been slightly diluted by the fact that purchases were made for an entire household. The youngest age group seemed to have replaced red meat to a large extent with poultry and plant-based food alternatives, but not with fish. This may indicate a slow intergenerational change.

Our results indicate a slow road with tiny steps from meat dominance to more sustainable diets. This was reflected by our findings of a mixture of prevalent profiles, with the highest persistence of the red meat preference. The most likely departure from red meat was towards poultry, followed by fish and plant-based foods. This supports earlier findings of the tendency to use a hierarchy of foods when substituting meat; food is often substituted on a plate by another familiar product with a similar component structure (42, 43). These hierarchical steps are more likely than leaps, especially among the older generation.

The step-by-step approach should be valued when designing health communication and steering methods. Switching to poultry and fish must be presented as an attractive, affordable and socially valued option since a direct switch to plant-based foods might be too much of a leap for most consumers. While information and education are critically important means, shifting attention also to consumers' everyday practices and habits is important to generate long-lasting shifts (44).

343 Shifting towards sustainable food choices requires multilevel national and international
344 collaboration between all stakeholders (45). Dietary guidelines that reflect the latest evidence
345 on healthy eating complemented with broader and more explicit criteria of sustainability can
346 be important macro-level tools for improving health and environmental sustainability (11,

16

347 45). Taxation may be an effective way to enhance major changes, given that alternative348 products are markedly cheaper (46).

349 Sustainability goals also call on food retailers to engage in social responsibility by extending 350 their focus from addressing consumers' preferences to the common good. Grocery store 351 interventions that manipulate price and item availability, or suggest swaps, have an impact on 352 purchase behavior (47). Food retailers' use of loyalty card data to uncover consumer 353 preferences could be utilized to design effective promotional activities, e.g. individual 354 feedback, or tailored price discounts that facilitate consumers' change towards more healthy 355 or sustainable preferences. This could help the food retailer to build competitive advantage to 356 other retailers (48). Indeed, several aspects may have already accelerated the transition towards a more sustainable diet since our data collection in 2016-2018. The market value for 357 358 plant-based products has been estimated to grow 7% annually in 2019-2021 (49), and the 359 supply and affordability of more sustainable foods have most likely improved. An 360 encouraging finding was that we observed a slight increasing trend within the 2.3-year follow-361 up in the persistence of the plant-based food preference. Moreover, disruptions to food 362 systems caused by the COVID-19 pandemic create opportunities to drive longer term 363 transformation (50).

Strengths of this study include a remarkably large dataset and a long and detailed follow-up period. Automatically collected data such as these will likely become complementary to selfreported data in future evaluations of health and sustainability issues, and it is therefore important to develop visualization and analysis methodology to use these data efficiently. The choice of methodology from another field of science may provide new insight into unconventionally structured data on food consumption or such surrogates as loyalty card holder purchases (51).

17

371 We have demonstrated that loyalty card data on grocery purchases reasonably well reflects the 372 self-reported food and drink consumption of the adult population (52, 53). However, purchase 373 volume does not correspond to consumed volume. The preparation of food may lead to 374 marked changes in weight (54). Consequently, the share of plant-based foods may be 375 underestimated and that of meat and fish overestimated. We believe that the profiles identified 376 in our study could be generalizable to similar consumer environments such as the Nordic 377 countries, where consumer culture is influenced by the Nordic societal model of strong 378 welfare system, relatively open markets, and relatively egalitarian stance to social differentiation (55). 379

We focused on four protein sources with clearly distinct environmental and health impacts. 380 381 Increasing the consumption of more climate-neutral foods, such as whole grains, could also 382 contribute to meeting environment-focused sustainability targets without compromising the 383 healthiness of the whole diet (3). In future studies, the whole-diet approach should be 384 preferred. We applied single questions to measure nutrition literacy and attitude towards a 385 topic, which were insufficient for assessment on a broader level. Further research should 386 apply well-defined and theoretically grounded measures (16). A limitation of the study is that 387 the participants were more likely women and more highly educated than the general adult Finnish population (27). A sensitivity analysis using a full re-weighting (27) showed that our 388 389 results on the prevalence of red meat and plant-based profiles could be slightly 390 underestimated and overestimated, by five and two percentage points, respectively. Other 391 profiles had a similar prevalence in the two analyses.

To conclude, although red and processed meat dominated the purchase preferences and
showed the highest persistence, there are promising signs for a shift towards more sustainable
diets. Consumers' attitudes are set for a change, and many plant-based foods are affordable

18

395 regardless of income. Reducing the price difference between the most commonly purchased 396 red meat and fish products could further accelerate this development. It is important to ensure 397 ways for today's young "greener" generation to maintain and strengthen the commitment to plant-based foods as they enter middle-age and face a hectic family life. Societal incentives 398 399 for sustainable food choices seem most crucial at transition stages of life course and for the 400 less educated. The world's future protein supply is an extremely challenging interplay 401 between ecological, social, cultural, and economic sustainability and the necessary nutritional 402 demand for high-quality protein. Up-to-date individualized grocery purchase data offer a 403 means for developing, implementing, and monitoring progressive policies towards a healthy 404 and sustainable food system. 405 Acknowledgements 406 We thank the S Group for collaboration. We are also grateful to the loyalty card holders who 407 provided consent for the use of their loyalty card data in this research project. 408 **Author contributions** 409 ME, HS, MF and JN were involved in the data collection and transfer. ME and JN were responsible for the design of the study, wrote the first draft of the manuscript, and had 410 411 primary responsibility for the final content. JN was responsible for the analyses of the study. 412 All authors participated in commenting and critically revising the first draft of the manuscript, 413 and read and approved the final version. 414 **Conflict of interest** 415 HV has received a fee from the S Group. The collaboration included offering professional 416 advice to influencers and writing a blog post with regard to interpretation of nutrition 417 calculator in S Group's mobile app. MF is a member of the S Group's Advisory Board for 418 Societal responsibility. The membership is without any compensation. The authors declare no 419 other relationships or activities that could appear to have influenced the present work.

Table 3. Mean (standard deviation) of participants' purchase price (\notin /kg) by purchase profile and food group.

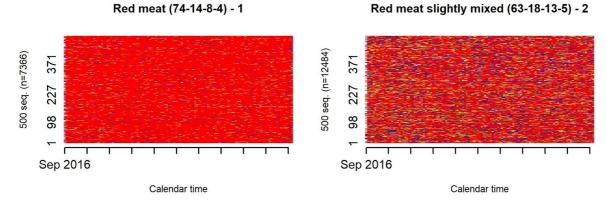

29

Table 4. Persistence (shaded cells) and transition probabilities from a purchase preference one week to a preference in the subsequent week. Missing preferences are not displayed; hence, the row probabilities do not add up to unity.

	To red meat	To poultry	To fish	To plant-based
From red meat	0.82	0.08	0.05	0.03
From poultry	0.35	0.48	0.08	0.05
From fish	0.31	0.11	0.46	0.08
From plant- based	0.24	0.08	0.10	0.53

30

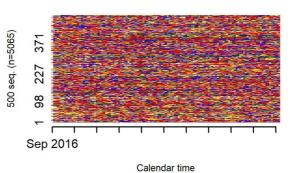

Figure 1. Purchase profiles identified by the sequence analysis, sorted from the least to the most sustainable. Each row in a panel represents an individual sequence of preferences with each week assigned the colour of the preference; 500 sequences per cluster are shown. The proportion of each food group (% of volume [kg] R-P-F-PB) is shown in the title. R = red meat and processed meat, P = poultry and poultry dishes, F = fish and seafood, and PB = plant-based foods.

Red meat and poultry (44-39-11-6) - 3

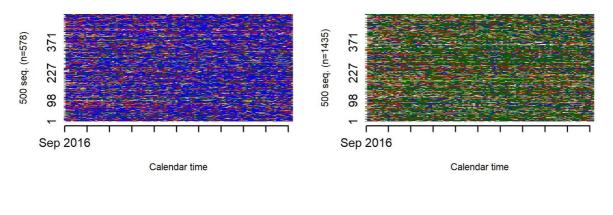

Plant-based (17-5-13-65) - 6

Missing	Poultry preference	Plant-based food preference
Fish preference	Red meat preference	

Figure 2. Frequency distribution (%) of attitude ("To promote health, the consumption of fish should be increased and that of red meat and processed meats limited") and nutrition literacy ("Recommended dietary changes include increasing the consumption of pulses") within clusters.

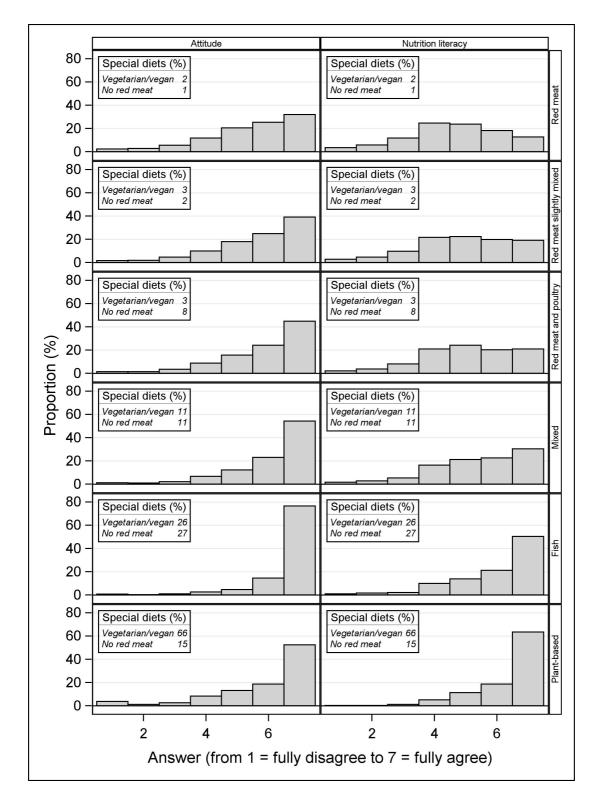

Figure 3. Odds ratios and their 95% confidence intervals from the ordinal logistic model. Odds ratios >1 indicate that the factor studied was associated with more sustainable, including a smaller proportion of red meat, purchase profiles. Reference class: single households and the lowest level in each factor. Full model includes all variables: demographic, resources, attitude, and nutrition literacy.

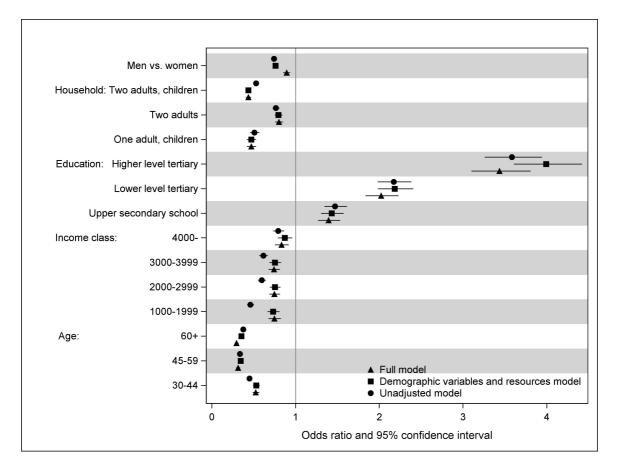

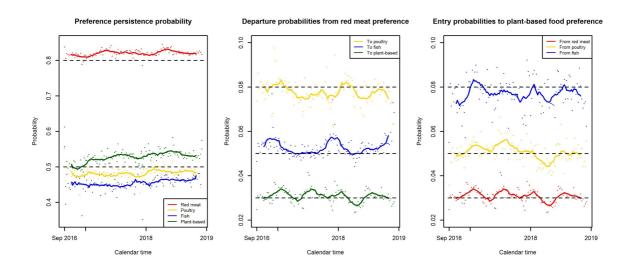

Figure 4. Estimated probabilities of persistence of, departure from, and entry to a preference from one week to the next by calendar time. Points indicate probabilities by week, and solid lines their 12-week moving averages.

Supplemental Figure 1. The flow of participants in the current study.
