13 Abstract

Background: Structural changes caused by spinal curvature may impact the organs within the thoracic cage, including the heart. Cardiac abnormalities in idiopathic scoliosis patients are often studied post-corrective surgery or secondary to diseases. To investigate cardiac structure, function, and outcomes in participants with scoliosis, phenotype and imaging data of the UK Biobank (UKB) adult population cohort was analysed.

20 Methods: Hospital episode statistics of 502,324 adults were analysed to identify 21 participants with scoliosis. Summary 2D cardiac phenotypes from 39,559 cardiac 22 magnetic resonance imaging (CMR) scans were analysed alongside a 3D surface-23 to-surface (S2S) analysis.

24 Results: A total of 4,095 (0.8%, 1 in 120) UKB participants were identified to have all-25 cause scoliosis. These participants had increased lifetime risk of major adverse 26 cardiac events (MACE) (HR=1.45, P<0.001), driven by heart failure (HR=1.58, 27 P<0.001) and atrial fibrillation (HR=1.54, P<0.001). Increased radial and decreased 28 longitudinal peak diastolic strain rates were identified in participants with scoliosis 29 (+0.29, P_{adi}<0.05; -0.25, P_{adi}<0.05; respectively). Cardiac compression of the top and 30 bottom of the heart and decompression of the sides was observed through S2S 31 analysis. Additionally, associations between scoliosis and older age, female sex, 32 heart failure, valve disease, hypercholesterolemia, hypertension, and decreased 33 enrolment for CMR, were identified.

34 Conclusion: The spinal curvature observed in participants with scoliosis alters the 35 movement of the heart. The association with increased MACE may have clinical

It is made available under a CC-BY 4.0 International license .

- 36 implications for whether to undertake surgical correction. This work identifies, in an
- 37 adult population, evidence for altered cardiac function and increased lifetime risk of
- 38 MACE in participants with scoliosis. Future genetic analyses would aid to assess
- 39 causality.

42 Introduction

43 Scoliosis is the lateral curvature of the spine with a Cobb angle >10°, primarily 44 diagnosed in adolescents[1]. There are multiple aetiologies of scoliosis including 45 neuromuscular, congenital, syndromic, or secondary to other diseases such as 46 muscular dystrophy or Friedreich's ataxia[2]. However, the most common type is 47 idiopathic scoliosis, with a prevalence of 8% in adults aged over 40 years old[3–5]. In 48 later life, scoliosis can result from skeletal muscle diseases such as sarcopenia. 49 Sarcopenia is the loss of muscle mass associated with age that may cause 50 imbalance and alteration on the supportive muscles of the spine, contributing to the 51 progression of degenerative scoliosis in elderly patients[6,7]. Degenerative scoliosis 52 is observed in 68% of adults aged over 60 years old, as the joints and disks of the 53 spine begin to deteriorate[7]. Osteopenia, loss of bone density, is more frequently 54 observed in females and contributes to the severity of the curvature of the spine[8]. 55 Furthermore, the coexistence of congenital heart disease (CHD) and spinal 56 curvature is found in up to 12% of infant and juvenile scoliosis patients presenting 57 with CHD[9,10]. This is likely due to shared developmental aetiology, whereas 58 studies are lacking on the impact of age-related scoliosis on the functioning of a 59 developmentally normal heart.

60

In addition to impacting physical day-to-day activities, structural disruption of the thoracic cage (pectus deformity) can influence the organs within, such as the heart[11]. Pectus deformities lead to the displacement of the heart towards the left side of the body which can result in right-sided spinal curvatures as the beating heart pushes the thoracic vertebrae to the right[7,11]. Furthermore, the degree of curvature of the spine can greatly increase the risk of restrictive lung disease, which

It is made available under a CC-BY 4.0 International license .

67 in conjunction with intrathoracic organ displacement, increases the risk of 68 comorbidities with high mortality rates, such as right heart failure[3,12].

69

70 The impact of scoliosis on adult cardiac function has not been extensively studied 71 and the relationship between scoliosis and non-congenital cardiac manifestations is 72 not well characterised. In the UK Biobank adult population cohort, we explored 73 whether all-cause scoliosis has an impact on or relationship with cardiac phenotypes 74 of the matured adult heart. We identify altered radial and longitudinal peak diastolic 75 strain rates and an increased lifetime risk of major adverse cardiovascular effects 76 (MACE) in participants with scoliosis in the UK Biobank. In addition, we observe 77 associations between scoliosis and older age, female sex, heart failure, valve 78 disease, hypercholesterolemia, diagnosis of hypertension, and decreased enrolment 79 for cardiac magnetic resonance imaging.

80 Methods

81 The UK Biobank population cohort

The UK Biobank (UKB) recruited over 500,000 participants aged 40-69 years across the UK between 2006-2010 (National Research Ethics Service, 11/NW/0382, 21/NW/0157)[13]. This project was conducted under the UK Biobank applications 47602 and 40616. All participants provided written informed consent[14].

86

87 UK Biobank codes for identification of scoliosis

A diagnosis of scoliosis was identified for UKB participants through the first occurrence of scoliosis trait (M41*), a composite trait of the first reported date derived by the UKB that incorporates data from primary care, hospital inpatient admissions, death records, and self-reported medical conditions (**Table 2**).

92

93 Cardiac magnetic resonance imaging data

94 Amongst all UKB participants, 39,559 participants had cardiac MRI (CMR) data 95 available[15]. Imaging was performed using a 1.5 Tesla machines (MAGNETOM Aera, Siemens Healthcare)[15], and 2D summary CMR traits were analysed for an 96 97 association with scoliosis. This includes left ventricular ejection fraction (LVEF), left 98 ventricular end systolic volume (LVESV), left ventricular end diastolic volume 99 (LVEDV), and measures of cardiac strain: Eulerian radial strain (Err), Eulerian 100 longitudinal strain (EII), Eulerian circumferential strain (Ecc), radial peak diastolic 101 strain rate (PDSR_{rr}), and longitudinal peak diastolic strain rate (PDRS_{II}). All CMR 102 traits were adjusted for age at the time of imaging, sex, White British ancestry, 103 systolic blood pressure (SBP), and body surface area (BSA).

104

It is made available under a CC-BY 4.0 International license .

105 Surface to surface analysis

A mass univariate regression was utilised to explore associations between the threedimensional (3D) mesh-derived phenotype and scoliosis[16–19]. The underlying principle of this approach is the implementation of a linear regression at each vertex of the 3D atlas to derive a regression coefficient associated with the variable of interest, which results in a map of beta-coefficients showing the strength and direction of these associations. The analysis was adjusted for age at the time of imaging, sex, White British ancestry, BSA, diastolic blood pressure (DBP), and SBP.

113

114 Lifetime risk and survival analyses

115 Lifetime risk of disease, from birth month to January 2021, was assessed using the 116 first occurrence of scoliosis trait (M41*). The first occurrence of health outcomes 117 summary data in the UKB is reported using ICD10 codes[13]. The fields analysed for 118 the major adverse cardiovascular events (MACE) composite trait were as follows: 119 cardiac arrest, 146*; atrial fibrillation and flutter/arrhythmia: 148* and 149*; heart 120 failure, 150*; and stroke, 164*, as previously published[20]. The survival analysis was 121 conducted using MACE and death as the primary outcome. Survival and survminer 122 R packages were used to estimate hazard ratios (HR).

123

124 Statistical analysis

R programming language (version 3.6.0) and RStudio software (version 1.3.1073) were used for analyses. Categorical variables were assessed using Chi-Squared Test or Fisher's Exact Test and expressed as percentages. Continuous variables were assessed using Student's t-test and expressed as mean ± standard deviation

It is made available under a CC-BY 4.0 International license .

129 (SD). All P-values were adjusted using Bonferroni correction for multiple 130 comparisons where P_{adi} <0.05 was deemed significant.

In the association of disease analysis, all variables were adjusted for age at recruitment (UKB ID: 21022-0.0) and genetic data-derived sex (UKB ID:22001-0.0) using a multiple linear regression model. A separate multiple linear regression model for CMR traits was used to adjust for covariates at the time of imaging: age, sex, White British ancestry, SBP, and BSA.

It is made available under a CC-BY 4.0 International license .

136 **Results**

137 Prevalence of scoliosis in the UK Biobank

The prevalence of all-cause scoliosis in 502,324 participants of the UKB was 1 in 139 120 (n=4,095; 0.8%). Of the 4,095 participants with scoliosis, 1,489 (37%) were 140 diagnosed with scoliosis prior recruitment. From the total participants with scoliosis, 141 10 (0.2%) reported congenital scoliosis, 23 (0.6%) reported childhood scoliosis 142 (infantile and juvenile) and the rest reported scoliosis due to other causes later in life. 143 The most common scoliosis subtype was unspecified scoliosis reported by 2,685 144 (65.6%) participants (**Table 2**).

145

Participants with scoliosis were significantly older than the rest of the population (59.4 years old \pm 7.58; mean age 56.5 years old \pm 8.10; P_{adj}<0.01) and were more female (69% female in scoliosis cohort; 55% female in the rest of the UKB population; P_{adj}<0.01). Lifetime risk analysis showed that participants with scoliosis had significantly longer lives when compared to the rest of the population, regardless of sex (**Figure 1**).

152

153 We observed a significantly increased burden of heart failure (+4%, P_{adi}<0.001), 154 valve disease (+1%, Padj<0.001), hypercholesterolemia (+7%, Padj<0.001) and 155 diagnosis of hypertension (+13%, P_{adi}<0.001) in scoliosis participants, adjusted for 156 age and sex (Table 2). Although diagnosis of hypertension was significantly 157 increased, no significant differences were found with SBP or DBP, which may be due 158 to correction of diagnosed hypertension through medication. Additionally, the 159 proportion of scoliosis participants with CMR available was significantly decreased (-160 3%, P_{adi}<0.001) compared to the rest of the population.

It is made available under a CC-BY 4.0 International license .

161

162 CMR analysis of participants with scoliosis identifies altered cardiac diastolic strain 2D summary CMR traits were available on 39,559 participants[15]. 224 participants 163 164 with scoliosis had CMR available and had significantly increased radial PDSR 165 (P_{adi}<0.05) and decreased longitudinal PDSR (P_{adi}<0.05) compared to participants 166 without a diagnosis of scoliosis (Table 3). Adequate diastolic function is essential 167 during ventricular filling and maintenance of optimum stroke volume. PDSR is a 168 diastolic function trait, that has been previously associated with major adverse 169 cardiovascular events, increased mortality, increased blood pressure and altered left 170 atrial function [21]. For example, decreased PDRS_{rr} corresponds to stiffer ventricle, 171 impairing its relaxation and increasing the risk of heart failure[21]. No additional 172 significant associations were found with the other CMR measures available for 173 analysis and no association was observed between scoliosis and diabetes (Table 1).

174

175 Surface to surface analysis of participants with scoliosis shows increased cardiac176 compression

A 3D surface-to-surface analysis was performed on 21,088 participants of the cohort. The three-dimensional cardiac modelling of scoliosis patients showed increased strain at the top and bottom of the heart (**Figure 2**). Radial cardiac decompression (sides of the heart) was also observed in participants with scoliosis. However, these were not significant when adjusting for the number of comparisons and covariates.

182

183 Lifetime risk of MACE is increased in participants with scoliosis

A significantly increased lifetime risk of MACE was observed for UKB participants with scoliosis (**Figure 3**; HR=1.45, P<0.001), mainly driven by heart failure

It is made available under a CC-BY 4.0 International license .

(HR=1.58, P<0.001) and atrial fibrillation (HR=1.54, P<0.001). The probability of MACE doubled in males into older age (from 60 years of age). This may be caused through the altered cardiac diastolic strain rates observed in participants with scoliosis. However, we emphasise caution regarding the causality of this association of scoliosis and MACE at this stage.

It is made available under a CC-BY 4.0 International license .

191 Discussion

192 Participants with scoliosis have increased lifetime risk of MACE

To the best of our knowledge, this is the first study to identify an increased lifetime risk of MACE, through atrial fibrillation and heart failure, in participants with scoliosis. This may be through the identified, significantly increased PDSR_{rr} and decreased PDSR_{II}. The abnormal curvature of the spine can increase mechanical constraint on the heart which may result in diastolic dysfunction[22] and the severity of the spinal deformity has been shown to aggravate ventricular and right atrial pressure[3].

199

200 It is unlikely that the observed heart failure is due to blood pressure abnormalities as 201 no significant differences were found in measured SBP and DBP between 202 participants with scoliosis and the rest of the population. However, it is possible that 203 pulmonary dysfunction may be eliciting cardiac dysfunction alongside atrial 204 fibrillation, in patients with advanced scoliosis[3,11,23]. These findings suggest that 205 early medical intervention in patients with scoliosis through surgery, may decrease 206 the risk of a future MACE, however future validation of this finding would need to be 207 confirmed in a scoliosis case cohort. It may be possible that scoliosis develops 208 secondary to other diseases that could also increase the risk of MACE. Future 209 genetic analyses would be beneficial to assess causality through Mendelian 210 randomisation techniques. Likewise, studies are required to determine whether the 211 cardiovascular changes observed are reversible with scoliosis treatment surgery.

212

A previous study assessed 201 scoliosis patients for cardiopulmonary changes following corrective scoliosis surgeries and suggested that untreated scoliosis can result in pulmonary dysfunction and subsequently lead to right heart failure,

increasing mortality[3]. Postoperative normalisation of cardiac measures was observed in this study, highlighting the potential benefits of surgical correction of scoliosis on cardiac function[3]. Additionally, a long-term follow-up study showed increased risk of pulmonary limitations such as shortness of breath in patients with untreated scoliosis, aggravated by spinal curvature[24].

221

It is challenging to accurately assess the cardiac function of scoliosis patients, due to the heart being displaced[22] and participants with scoliosis in the UKB had significantly less CMR scans available, possibly due to lack of comfort for prolonged periods of time in MRI machines. Adaptations may be required to allow patients with scoliosis to undergo MRI scans more comfortably, to further assess any alteration in cardiac function in scoliosis patients.

228

229 Participants with scoliosis have altered cardiac diastolic strain rates

230 In the UKB, participants with scoliosis showed increased pressure at the top and 231 bottom of the heart, as well as elongation of the sides of the heart. These results 232 concur with the 2D-derived CMR findings of significantly increased PDSR_{rr} and 233 decreased PDSR_{II}. A reduced PDSR_{II} has been previously associated with reduced left atrial function[21]. No significant associations were found with the other studied 234 235 CMR traits, suggesting that this compression does not alter blood flow through the 236 heart. This altered cardiac strain may be explained by the deformity of the thoracic 237 cage in scoliosis limiting cardiac diastolic movement. The mechanical abnormalities 238 of the thoracic spine as well as the impact on the pulmonary system, may be the 239 primary cause of the heart involvement[25,26]. Secondary involvement via altered 240 pulmonary haemodynamics may be possible, where spinal curvature impacts

pulmonary pressures leading to pulmonary hypertension. Likewise, direct compression of the myocardium could occur in conjunction to pulmonary involvement. These events can contribute to the development of cardiac consequences in scoliosis patients[27]. It would be beneficial to include cardiac follow-ups in patients with scoliosis to observe any cardiac alterations as scoliosis progresses, ensuring early intervention.

247

248 Prevalence of scoliosis in the UK Biobank

We report a prevalence of scoliosis of 0.8% in the UKB population cohort. Previous literature has reported a scoliosis prevalence of 8% in adult volunteers aged over 40 years old[5]. Patients included in the previous clinical study were recruited on evaluation of bone mineral density and thus were likely at increased risk of scoliosis. Additionally, this discrepancy may be due to limitations of the UKB cohort (see *Limitations*).

255

Participants with scoliosis in the UKB are more elderly compared to the rest of the population, regardless of sex. Scoliosis occurs alongside other diseases such as osteoporosis or degenerative spine disorders with increasing age[5].

259

In the UKB cohort, scoliosis is more commonly found in females than males (2.5:1), which agrees with a previous scoliosis case cohort study of adolescents and adults that reported a ratio of scoliosis in females to males as 2:1[28]. Although not fully understood, there are different theories linking the higher prevalence of scoliosis in females, including implication of the autonomic nervous system (ANS) in skeletal growth and/or puberty through leptin hormone, which has been found decreased in

It is made available under a CC-BY 4.0 International license .

female patients with idiopathic scoliosis[1,29,30]. The role of leptin in scoliosis is not fully understood, and analyses to determine causality would aid our current understanding of the mechanisms behind scoliosis. Furthermore, it has been reported that approximately 30% of females (n=324) suffer from systemic osteopenia which strongly contributes to the progression of spinal curvature in adolescent females following skeletal maturity[8].

272

273 Limitations

The participants in the UKB cohort were recruited at 40-69 years of age and most participants are of European ancestry. Selection bias for inclusion in CMR sub cohort may have excluded more severe scoliosis participants from study. In addition, discrimination of scoliosis aetiology was mostly unspecified.

278

279 Conclusions

This work describes for the first time in an adult population, evidence for altered cardiac function in adult participants with scoliosis. We identified altered diastolic strain, increased lifetime risk of MACE driven by HF and atrial fibrillation and observed cardiac compression in the UK Biobank participants with scoliosis. Further research is required to follow up the role of scoliosis in cardiac manifestations in a clinical setting.

394 Tables

Table 1 Summary statistics of participants with scoliosis compared to the rest of the UK Biobank population cohort.

³⁹⁷ Data is presented as mean \pm SD or count (%); all the variables are adjusted for age ³⁹⁸ and sex; BMI, body mass index; SBP, systolic blood pressure; DBP, diastolic blood ³⁹⁹ pressure; CMR, cardiac magnetic resonance imaging; CM, cardiomyopathy. White ⁴⁰⁰ British ancestry was genetically inferred. P_{adj}, P-value adjusted for multiple ⁴⁰¹ comparisons via Bonferroni correction; Significant, P_{adj}<0.05; NS, not significant, ⁴⁰² P_{adj}>0.05.

Characteristic	General population	Scoliosis carriers	P_{adj}
	(n=502,324)	(n=4,095)	
Age at recruitment	56.50 ± 8.10	59.40 ± 7.58	<0.001
White British	406,131 (81%)	3344 (82%)	NS
Sex, female	261,862 (55%)	2,845 (69%)	<0.001
BMI	27.40 ± 4.80	27.00 ± 5.16	NS
Auto SBP	140.00 ± 19.60	141.00 ± 20.00	NS
Auto DBP	82.20 ± 10.70	81.50 ± 10.80	NS
Diabetes	27,771 (5%)	212 (5%)	NS
Hypercholesterolaemia	92,824 (18%)	1,022 (25%)	<0.001
Hypertension	167,817 (33%)	1,902 (46%)	<0.001
Included in UKBB CMR cohort	39,319 (8%)	224 (5%)	<0.001
Heart failure	10,504 (2%)	237 (6%)	<0.001
Any CM	3,602 (0.7%)	49 (2%)	NS
Valve disease	5,145 (1%)	96 (2%)	<0.001

404 **Table 2: Codes used for identification of all-cause scoliosis.**

The HES data is coded using the International statistical Classification of Disease (ICD) codes, versions 9 and 10. The self-reported data (SR) has a UKB-specific coding system. SR, non-cancer illness code, self-reported data; ICD9, summary diagnoses (main and secondary); ICD10, underlying primary cause of death, contributory cause of death, and external cause of death, summary diagnoses (main and secondary); GP, general practitioner.

Disease/phenotype	Participants (n=4,095)	Coding system
Self-reported scoliosis	468 (11.4%)	SR: 1535
Kyphoscoliosis and scoliosis Congenital postural scoliosis	5 (0.1%) 0 (%)	ICD9: 7373, 75420
Congenital scoliosis	10 (0.2%)	ICD10: Q763, M965, M41,
Post-radiation scoliosis	10 (0.2%)	M410, M4100-109, M411,
Childhood scoliosis	23 (0.6%)	M4110-119, M412, M4120-
(infantile and juvenile)		129, M413, M410-139, M414
Other idiopathic scoliosis	56 (1.4%)	M1410-149, M415, M1450-
Thoracogenic scoliosis	24 (0.6%)	159, M418, M4180-189,
Neuromuscular scoliosis	22 (0.6%)	M419, M4190-199
Secondary scoliosis	79 (2%)	
Other forms of scoliosis	226 (5.5%)	
Unspecified scoliosis	2685 (65.5%)	
Unspecified scoliosis	487 (11.9%)	GP-derived

412 Table 3: Summary of the altered cardiac PDSR in participants of the UKB with

413 scoliosis.

414 Mean and standard deviation for adjusted PDSRs are described for the general UKB

415 population and participants with all-cause scoliosis. The p-value was adjusted for

416 multiple comparisons of CMR traits. WT, wall thickness; LVEDV, left ventricular end-

417 diastolic volume: LVEF, left ventricular ejection fraction; LVM, left ventricular mass;

418 Ecc, circumferential; Err, radial; Ell, longitudinal; PDSR_{II}, longitudinal peak diastolic

419 strain rate; PDSR_{rr}, radial peak diastolic strain rate.

420

CMR trait	General population (n=38,319)	Scoliosis (n=224)	P_{adj}
Maximum WT	9.40 ± 1.62	9.36 ± 1.70	NS
LVEDV	148.00 ± 33.90	136.00 ± 32.80	NS
LVEF	59.50 ± 6.16	59.80 ± 6.03	NS
LVM	86.0 ± 22.30	78.00 ± 20.70	NS
Ecc Global	(-22.33) ± 3.35	(-22.10) ± 3.77	NS
Err Global	45.00 ± 8.31	45.20 ± 8.73	NS
Ell Global	(-18.50) ± 2.76	(-17.90) ± 2.44	NS
PDSR	1.66 ± 0.61	1.45 ± 0.58	<0.05
PDSR _{rr}	-5.64 ± 2.09	-5.08 ± 2.13	<0.05

422 Figure legends

Figure 1: Scoliosis is associated with longer life compared to the rest of the UKB cohort, adjusted for sex.

Years of life is shown on the x-axis from date of birth. Counts of UKB participants are shown in the box depicting number at risk. The median survival time (a survival probability of 0.5) was significantly increased in participants with scoliosis, regardless of sex. Median survival time for females with scoliosis vs females without scoliosis (2 years difference); median survival time for males with scoliosis vs males without scoliosis (1.5 years difference).

431 Figure 2 Surface to surface analysis suggests a compressed heart in 432 participants with scoliosis.

3D models of left ventricle geometry with standardized beta-coefficients which show
the association between scoliosis and regional surface-to-surface distance. Blue,
increased inward pressure; red, increased outwards pressure.

436

437 Figure 3: Increased lifetime risk of MACE in UKB participants with scoliosis.

438 A, cumulative incidence curve depicts an increase in lifetime risk of MACE in 439 participants with scoliosis over time (HR=1.45, P<0.001). B, incidence curve 440 stratified by sex (HR=1.63, P<0.001).

Exploration of the impact of scoliosis on the heart in the UK Biobank

4,095 (1 in 120) participants have scoliosis in the UK Biobank with: Increased risk of major adverse cardiovascular events (HR=1.63) Mainly driven by heart failure (HR=1.58) and atrial fibrillation (HR=1.54)

Cardiac magnetic resonance imaging Diastole

No spinal curvature

Scoliosis

Surface to surface analysis

Identification of increased cardiac compression on the top and bottom of the heart, and radial cardiac decompression (sides of the heart) in scoliosis patients.

Conclusion:

This work identifies, in an adult population, the evidence for altered cardiac function and increased lifetime risk of MACE in participants with scoliosis.
