## Abstract

Malawi HIV treatment guidelines recommend same-day antiretroviral therapy (ART) initiation. Overall 97.9 % of Malawians living with HIV (PLHIV) are on ART, same-day ART initiation prevalence and factors that facilitate it have not been fully described. We assessed same-day ART initiation and described individual, health system and health facility infrastructural factors at health facilities supported by expert clients (EC). ECs are lay PLHIV who support other PLHIV. The study was conducted in urban and semi-urban primary health facilities, in Blantyre, Malawi. It was a cross-sectional, descriptive survey of PLHIV and health facility leaders. Eligibility criteria included age  $\geq 18$  years, new diagnosis of HIV, received counselling from ECs, and offered same day ART. The study was conducted from December 2018 to June 2021, and 321 study participants enrolled. Mean age (standard deviation) was 33 years (10) with 59% females. In total, 315 (98.1%) initiated same day ART. Four participants did not because of mental unpreparedness, one wanted to try herbal medicine and one was concerned about stigma. Participants reported health facility accessibility (99%, 318/321), privacy (91%, 292/321) and quality of counselling by EC as excellent (40%, 128/321). Same day ART was nearly universal. Participants' satisfaction with health services delivery, the presence of EC, and infrastructural characteristics such as good privacy were cited as reasons favoring same day linkage to ART. The most cited reason for not starting same day ART was mental unpreparedness.

**Key words:** Linkage to care, HIV, Malawi, Expert client, HIV counseling, Same-day, Antiretroviral therapy.

## Near-universal same day linkage to ART care among newly diagnosed adults living with HIV in urban Malawi

### Introduction

According to UNAIDS, in 2020, there were an estimated 25.6 million people living with HIV (PLHIV) in the Africa region (1). In Malawi, HIV prevalence among adults aged 15-49 years is 8%, and 97.9% of PLHIV are taking antiretroviral therapy (ART) (2). Prevalence of HIV is highest in Blantyre at 14.2% (2). A reason for high ART adoption in Malawi is the adoption of the WHO HIV Test and Treat Approach in 2016, which promotes rapid initiation of ART within 7 days of HIV diagnosis (3). WHO also strongly recommends ART commencement on the same day as HIV diagnosis, after health workers have established the person's willingness and readiness to start ART (4).

Same day initiation has advantages, although studies in sub-Saharan Africa (SSA) have found that same day ART initiation is low and ranges from 41.9% to 54.2% (4). In Malawi, data are limited; one study in 2016 found that same day ART initiation for pregnant women had prevalence of 63% (5). One strategy used in Malawi to improve ART initiation rates has been to deploy expert clients (ECs) in 29 health facilities in Blantyre district. ECs are lay individuals living with HIV, open to disclosing their HIV status, and with good records of ART adherence. They are trained as volunteer ART counsellors, offering the unique approach of a peer from the same community, and sharing their own experience of living with HIV (8). ECs talk to other PLHIV on their experience of living positively with HIV, providing them with a better understanding of the disease and less fear of disclosure (6). At health facilities where ECs are deployed, their roles may include provision of extra post-test counselling, and assistance with navigating and/or escorting patients to the different rooms providing HIV-related services. The EC model provides task shifting from overburdened health workers by supplementing to the posttest counselling done by the HIV testing and

counselling providers (HTC) (8). The EC model has been used successfully in Swaziland, Zambia, Botswana, Uganda and South Africa (7) as well as in pilot studies in Balaka and Machinga, rural districts in southern region of Malawi (6). Malawi has achieved the second 95% of the UNAIDS goals in 2020/21 as 97.9 % of PLHIV are on ART (2), providing evidence that after diagnosis, most people do eventually initiate ART, even if it may not be on the same day of diagnosis. There are about 2.1 % of PLHIV who are not on treatment, posing a risk of morbidity and mortality in these individuals and HIV transmission to others.

There is need to investigate same-day ART start in Malawi and identify factors, including EC, which may be associated with same day linkage to ART care. The understanding of these determinants will allow targeted improvements in this key metric, and will improve health system efficiency to allow health centers to continue to serve high numbers of clients (8). Our study sought to assess same day ART linkage prevalence, and describe individual, health care center, and systems factors influencing same day linkage to ART care among PLHIV in primary health care facilities supported by EC.

## Methods

The study was a quantitative descriptive cross sectional study design, conducted at Limbe and South Lunzu health facilities within Blantyre district, Malawi. South Lunzu (semi-urban) initiates about 35 people per month on ART, and Limbe (urban) primary health care facilities provides care to an average of 100 newly diagnosed PLHIV per month. The facilities have HIV testing and counselling (HTC) clinics where the following services are provided: (1) group counselling (2) pre-test counselling (3) testing and (4) posttest counselling. All these services are conducted in a separate counselling room, by an HTC provider. Patients that are newly diagnosed with HIV are then referred to the ART provider, who sits in a separate room, to

commence ART. Patients may accept or decline ART, whatever their choice, they are asked to visit the EC first, for peer counselling, before they visit the ART provider. Participants were approached for the study after their session with the EC. All HIV newly diagnosed adults from South Lunzu and Limbe health facilities were approached for screening. Additional inclusion criteria were: adults of over 18 years of age, newly diagnosed of HIV, provided with extra counselling by an EC and willing to provide written informed consent. Additional facility-level data was collected from leaders of each health facility.

## Sample Size

We used a single population formula to calculate the number of participants needed to determine prevalence of same day ART acceptance. We assumed same day ART initiation would be 63% based on the previous Malawian study (9). The calculated sample size was 298 participants. By adding a 10% non-response rate, the sample size was arrived at 328.

## Data collection, management and analysis

Two study staff at each facility recruited participants and then conducted interviews with participants after their session with the EC. Those willing to start same day ART then proceeded to the ART provider room, while those unwilling left for their homes. Participants filled a questionnaire with comprehensive socio-demographic data and HIV stigma information. Participants' experience at the health center, including waiting time, and medication stock outs, was also assessed as well as the health infrastructural characteristics which included accessibility and privacy. The main outcome variable was same-day ART initiation, with categorical response of (Yes, No), verified by staff or health book. Questionnaires and checklists were filled out using Open Data Kit (ODK). and imported into STATA version 14.2 for analysis. Using STATA,

descriptive data were summarized using proportions and means of the whole study sample, those linked to ART and those not linked to ART where appropriate.

## Ethics

Ethical approval to conduct the study was obtained from Kamuzu University of Health Sciences, College of Medicine Ethics Committee (COMREC). All study participants gave written informed consent in Chichewa language.

## Results

The study was conducted from December 2018 to June 2021. A total of 333 newly-diagnosed PLHIV were approached to take part in the study, and 321 (96%) accepted study participation, including 161 participants from Limbe and 160 from South Lunzu. More participants from Limbe declined participation (4.9%, 8/161) compared to South Lunzu (2.5%, 4/160). Reasons for declining included not interested (8/12), in a hurry (3/12) and wanted husband's consent (1/12).

## Characteristics of study participants

The baseline characteristics of the participants are shown in Table 1. The mean age (standard deviation [SD]) of participants was 33 years (10), most were female (59%, 189/321) and the majority had a source of income (67%, 215/321). Study participants reported taking the HIV test on a voluntary basis (66%, 211/321) as opposed to provider initiated, and most accepted their HIV results (99%, 318/321) and knew someone on ART (77%, 246/321). A few study participants reported fear of stigma (5%, 17/321) related to disclosure of HIV status.

140 Table 1: Descriptive socio demographic characteristics of persons newly diagnosed with HIV at  
141 primary health care centers in Blantyre, Malawi.

Sociodemographic characteristic ( N=321)	n (%) or mean (SD)

## 145 **Linkage to ART**

146 There were 315 out of 321 participants who initiated ART on the same day of HIV diagnosis, this  
 147 represents a total linkage point prevalence of 98.1%. Prevalence of same-day linkage for Limbe  
 148 health facility was 97.5% (157/161) while that of South Lunzu was 98.75% (158/160). There were  
 149 6 people who were not linked to ART for the following reasons: 67% (4/6) were mentally not  
 150 ready to start ART immediately, 17% (1/6) wanted to use herbal medicine and another 17% (1/6)  
 151 was afraid of stigma. The mean age (SD) of those not linked to ART did not differ from those who  
 152 did accept ART: 32 years (7) and they were predominantly female (67%, 4/6).

## 153 **Views of Health Care Workers and clients regarding performance** 154 **of health systems on ART**

155 Through the checklist, health facility leaders reported that Limbe had a total of 18 HTC, 35 ART  
 156 providers and 10 ECs who worked 8 hours a day while South Lunzu had 9, 31 and 7, respectively.  
 157 On a single day, at Limbe health facility, there are on average 10 HTC counsellors, 10 ART  
 158 providers and 10 ECs, while at South Lunzu health facility, there are 3 HTC providers, 4 ART  
 159 providers and 7 ECs providing services. For both health facilities, there was no single day in the  
 160 first quarter of 2020 that HTC, ART and ECs services were not available. The participants rated  
 161 the counselling services provided by, and the quality of interaction between themselves and HCWs  
 162 and ECs (Table 2). The majority (74%, 238/321) of participants indicated that they waited for less  
 163 than 1 hour before they received services at the HTC clinic. ECs made contact with almost all  
 164 persons, with 97% (311/321) of participants indicating that they had received assistance from EC,

with directions and/or escort (navigation assistance) to different rooms for services. Those who wanted to continue ART at a different facility were still able to initiate same day ART, with an established referral system of patients who get diagnosed at one facility but would like to receive their ART from another. The health care workers also agreed that in the first quarter of 2020 there were no stock outs of HIV testing materials or ART drugs.

Table 2: Rating by study participants of counselling services provided by HCWs and of quality of interaction between the study participants and HCWs

Score, n (%)	Excellent	Good	Average	Bad	Total
Quality of counselling by EC*	127 (39.56)	191 (59.50)	2 (0.62)	1 (0.31)	321 (100)
Quality of counselling by HTC** providers	112 (34.89)	207 (64.49)	2 (0.62)	0 (0.00)	(321) 100
Quality of interaction with EC	134 (41.74)	185 (57.63)	2 (0.62)	0 (0.00)	(321) 100
Quality of interaction with HTC providers	125 (38.94)	194 (60.44)	2 (0.62)	0 (0.00)	(321) 100

## Description of Health facility infrastructural characteristics by study participants

Study participants described infrastructural characteristics (Table 3) which included: health facility accessibility, privacy in accessing ART services and conduciveness of the distances and location of some rooms where HTC services were provided. Most participants found the health facility accessible (99%, 318/321) and the distance between ART room and HTC clinic conducive (85%, 274/321).

Table 3: Opinions of study participants about their experience of facility infrastructure

## Discussions

In this study, we found that same-day linkage to ART of newly diagnosed PLHIV was very high (98.1%). We also found that most participants had very positive views of the service delivery and infrastructure at the facilities, which may have facilitated linkage to care. The good services

described by study participants included counselling services, clinic navigation and conducive and accessible health facilities. The health facility leaders described adequately staffed facilities without ART and medical supplies stock outs. In total, participants and facility leaders described a well-functional infrastructure which promoted and enabled newly diagnosed persons to accept same day ART initiation.

This high same day ART initiation rate found in our study is in sharp contrast with findings from previous studies in SSA which found linkage rate ranging from 41.9%- 54.2% (4). Some prior barriers to same day initiation found in previous studies, included the need for newly diagnosed PLHIV to start ART at a different facility from where they tested(4). Studies conducted elsewhere in SSA have shown that participants who are tested in a health facility in which they are linked to ART services are two times more likely to initiate same-day ART compared with those tested from another health facility or in a community HIV testing setting and subsequently referred (4,9-10). In situations where newly diagnosed PLHIV require referral to another health facility for supply of their ART, Limbe and South Lunzu health facilities have an existent referral system whereby they would commence the patient on ART first and refer to another health facility for continuation of supply of ART. This may have contributed to the high linkage rate compared to previous studies in SSA that found low linkage rate. Another factor contributing to higher same day initiation is that this study setting was only primary healthcare facilities, while previous studies included primary and secondary healthcare facilities(4). Patients who present to primary healthcare facilities are more likely to have uncomplicated clinical presentation, making it easier for health workers to commence them on same day ART, unlike in a secondary health care facility, where health care workers may have to wait to conduct other investigations or stabilize the patient before ART is commenced(4). This is also in line with other studies that found that patients without opportunistic

infections were two times more likely to initiate same-day ART compared with patients with one or more opportunistic infections(4). Similarly, a study in South Africa reported that patients who presented with less advanced clinical disease were more likely to accept same-day ART initiation(10). However, such findings are in contrast with several qualitative studies conducted in Malawi and some SSA countries, that had reported the absence of symptoms or signs of ill health as a major reason for deferring same-day ART(5).

The finding that most participants had positive views about the health facility is consistent with findings from previous studies conducted in Malawi and other countries in SSA which found that patients' satisfaction with the quality of services, patient-health worker relationships, time efficiency at the facility, good coordination of the different services at the HTC clinic, availability of staff and supplies, and accessibility of health facilities all contribute to reducing barriers to ART initiation(8-9,12). The difference between our study and others is that ours further revealed that the majority of study participants were content with the privacy of the facility and especially the proximity of the HTC, EC and ART rooms. Unfavorable distance between these rooms can instill fear of inadvertent disclosure of HIV status and therefore have an impact on ART linkage rates.

The finding that four out of six participants who were not linked to ART did so because they were mentally not ready is consisted with findings of a study conducted in eastern and southern parts of Africa, which highlighted the fact that the process of HIV status acceptance takes time (7). The 'test and treat' approach has significantly removed the psychological component where one is required time to digest the news of their new HIV status and make their decision on ART(7). The participants who were not linked to ART on the day of diagnosis might have initiated ART later, but this was outside the mandate of our study.

Our facilities were supported with lay health workers (EC) and we found that they were a critical part of the health facility and may have contributed to the high same - day linkage through the support they provided to clients. Task-shifting to meet human resources for health facilities is recommended by WHO(12). Evidence encourages such task-shifting in HCT settings in LMIC in SSA that are mostly affected by the HIV epidemic, and have a critical shortage of skilled health care providers which provides additional efficiencies to the health services (13). Having these additional personnel to provide both emotional support and navigation services contributes to the smooth functioning of the health facility and contributes to supporting PLHIV on their day of diagnosis.

Our study provides insight on multi-dimensional factors associated with same day ART linkage in primary health facilities, but it had some limitations. This study did not explore community factors like family or community support structures that might affect same day ART initiation. The study participants described their facility experience, which could have been a source of social desirability bias. About 12 adults living with HIV, who were approached by study staff to participate in the study, refused. The linkage outcome to ART of these individuals is not known. It is important to note that there is potential for selection bias if the linkage outcome of these 12 individuals is similar. Our findings show that in an under-resourced lower income country, extremely high rates of same day ART start can be achieved at the primary health care facility setting. We suggest that participants' satisfaction with health services delivery and infrastructural characteristics may have favored linkage to ART of newly diagnosed PLHIV, and that primary health facilities supported by lay health workers can provide high patient satisfaction. Our findings also suggest that mental unpreparedness may contribute to unsuccessful linkage to ART. We recommend that health facilities must be supported with human resources, medical drugs and

supplies and appropriately designed infrastructure in order to deliver services optimally. Health facilities must be accessible and be designed in a manner that encourages privacy. Future directions could include research to determine what type of counselling is most effective in encouraging newly diagnosed patients to start ART on the same day as diagnosis.

## Acknowledgements

The authors would like to thank the study participants as well as the study team for their significant contributions to the study. We thank Alison Roxby MD at the HIV Vaccine Trials Network for editorial assistance. We also thank Dr Bonus Makanani for his contribution in the implementation of this research.
