ABSTRACT

Introduction: In Peru, one in six adults over 50 years old has cataracts. This proportion increases due to the lack of routine visual assessments among older adults. Therefore, the objective of this research was to evaluate the socioeconomic inequalities in visual assessments among older adults with cataracts in Peru. **Methods:** This analytical cross-sectional study was conducted using data from the Demographic and Family Health Survey in Peru from 2013 to 2023. Socioeconomic conditions such as gender, age, educational level, wealth quintile, area or place of residence, health insurance status, and comorbidities were evaluated. Inequalities were estimated using the concentration index (CI) and Erreyger's modification (ECI). **Results:** Of the 6,367 older adults with cataracts included in the study, 93.1% (95%CI: 92.2–93.9) had a visual assessment. The average age of the participants was 76.7 years, with over half of them being women (56.2%). Conditions such as educational level, wealth quintile, area or place of residence, and comorbidities mediated differences in the proportion of adults with cataracts who had visual assessments ($p < 0.001$). Adults without education (ECI: -0.16), residents of rural areas (ECI: -0.41), or those outside Lima (ECI: -0.51) exhibited greater inequalities in receiving visual assessments. **Conclusion:** Among older adults with cataracts, living in rural areas or outside Lima and having a low educational level were identified as key factors mediating greater inequality in visual assessments.

INTRODUCTION

By 2020, it is estimated that nearly 94 million people will be blind or visually impaired (1). The leading cause of this problem is cataract, a condition that can be managed with early detection, timely treatment, and surgical intervention (2, 3). While aging is a common factor, poverty, lack of education, and limited access to eye care can increase the risk of cataracts (4, 5). Thus, the gap in access to these services varies in the population according to income, educational level, age, sex, place or area of residence, and even ethnic identification, leading to disparities in eye care access (6–11).

The global prevalence of visual impairment due to cataracts ranges from 0.9% to 10.7%, reflecting differences in health-care systems, socioeconomic conditions, and availability of treatment (12). In South America, disparities in healthcare infrastructure, awareness, and treatment accessibility contribute to the varying prevalence of cataract-related blindness among older adults (13, 14). In Peru, 13.5% of the population has visual impairment, and one in six adults over 50 has cataracts, showing the heavy burden of eye conditions in the country (15, 16). Aging, delayed diagnosis, and health conditions such as diabetes significantly contribute to the increased prevalence of cataracts (17–23).

Current visual health guidelines in Peru do not adequately address the socioeconomic and health disparities in access to and utilization of eye care services (24–26). These differences in eye care can negatively impact older adults, reducing their quality of life, functional independence and increasing the risk

of accidents (27–31). This study aimed to assess socioeconomic disparities in evaluating the vision of older adults with cataracts in Peru, looking at differences in accessing eye care services and treatment results.

METHODS

Study Design

An analytical study was conducted using data from the Demographic and Family Health Survey (or ENDES, in Spanish) in Peru. The National Institute of Statistics and Informatics (or INEI, in Spanish) has been conducting the ENDES annually in Peru, a country in South America with approximately 32 million of inhabitants, with capital city is Lima (32). Therefore, we assessed Peruvian adults aged 65 or older with cataracts who were surveyed in ENDES between 2013 and 2023.

Variables Assessed

Within the survey, participants are asked whether they have 'been diagnosed with cataract' and whether a 'doctor or health professional has evaluated or measured your vision'. In addition, other variables were assessed, such as sex (male or female), age group (65 to 69, 70 to 79, and 80 or older), education level (no education, primary, secondary, or higher), wealth quintile (first, second, third, fourth, and last quintile), wealth quintile (first, second, third, fourth, and last quintile), area of residence (rural and urban), living in the capital city (yes or no), having health insurance (yes or no), and having a comorbidity such as overweight or obesity, hypertension, or diabetes mellitus.

Statistical Analysis

The analysis was performed using R Studio software version 4.2.2 (<https://cran.r-project.org/>), including the complex sample design of ENDES. Categorical variables were described using frequencies and percentages, with their respective 95% confidence intervals weighted by the design effect. In addition, the Rao-Scott test was used to assess differences in the proportion of adults with cataracts who had an ophthalmological examination between the categories of variables included in the study. We used Poisson regression models with large variances to look at the relationship between socioeconomic factors and eye exams. This helped us figure out the crude Prevalence Ratio (cPR) and the adjusted Prevalence Ratio (aPR).

Inequality Analysis

Inequality analysis utilized concentration curves to show the disparity in eye assessments based on socioeconomic status, ranging from the poorest to the richest wealth quintile. So, the concentration index (CI) was found by guessing the area above or below the curve. This way, the conditions that led to crowding above the curve showed how poverty affected inequality (33). Additionally, the Erreygers Concentration Index (ECI) was utilized to calculate inequality, considering the extremes of the population distribution across wealth quintiles for a more equitable assessment (34). Also, maps of Peru were generated to show the unequal geographic distribution of visual assessment among adults over 64 years old, along with the ECI distribution.

The study also evaluated disparities among participants with specific comorbidities like overweight, obesity, hypertension, and diabetes mellitus. Additionally, the study analyzed annual changes in the percentage of adults with cataracts who received eye exams and examined the related inequality indices to track trends over time.

Ethical Aspects

The study utilized data from ENDES, a national survey conducted with participants' informed consent, for its development. In addition, the study had no information to identify the participants included in the research.

RESULTS

Of the 6,367 older adults with cataracts examined (Appendix 1), more than half were female (56.2%, 95%CI: 53.7 to 58.7) and had a mean age of 76.7 years (95%CI: 76.3 to 77.0). In terms of socio-economic conditions, 39.9% (95%CI: 37.7 to 42.1) had completed secondary or higher education, and 56.0% (95%CI: 53.7 to 58.2) were in the first two wealth quintiles. Furthermore, approximately 84.2% (95%CI: 82.2 to 86.2) of the surveyed adults resided in urban areas, with around 47.1% (95%CI: 44.8 to 49.4) living in the capital. In addition, 87.7% (95%CI: 85.9

to 90.0) had health insurance, and 77.3% (95%CI: 75.2 to 79.9) had a comorbidity (Table 1). In addition, 64.0% (95%CI: 61.5 to 66.4) were overweight or obese, 46.5% (95%CI: 44.1 to 49.0) had high blood pressure, and 14.1% (95%CI: 10.8 to 18.3) had diabetes mellitus. Among older adults with cataracts, only six in 100 had no visual examination or measurement (6.9%; 95%CI: 6.1 to 7.8).

In addition, characteristics such as level of education, wealth quintile, region or place of residence, and presence of any comorbidity were found to mediate differences in the proportion of adults with cataracts who had an eye examination ($p < 0.001$). Specifically, older adults with cataract who had secondary education (aPR: 1.02; 95%CI: 1.00 to 1.04; $p = 0.047$), who lived in the capital city (aPR: 1.02; 95%CI: 1.01 to 1.04; $p = 0.004$), and who had any comorbidity (aPR: 1.04; 95%CI: 1.01 to 1.07; $p = 0.008$) were more likely to have had an eye examination. While those with no education (aPR: 0.91; 95%CI: 0.87 to 0.94; $p < 0.001$) or in the third (aPR: 0.97; 95%CI: 0.95 to 0.99; $p = 0.005$), fourth (RPa: 0.95; 95%CI: 0.91 to 0.98; $p = 0.002$), and fourth quintile (aPR: 0.95; 95%CI: 0.91 to 0.98; $p = 0.002$) were more likely to have had an eye examination. and the last quintile (aPR: 0.82; 95%CI: 0.77 to 0.87; $p < 0.001$) had a lower prevalence of an eye examination (Table 2).

Regarding the inequality of ophthalmological assessment in older adults with cataracts, a moderate inequality was found in those without ophthalmological assessment (Figure 1A). In addition, adults with only primary education (CI: -0.20), living in rural areas (CI: -0.97) or in regions outside Lima (CI: -0.41), and without health insurance (CI: -0.22) were more unequal in having an ophthalmological examination. On the other hand, those with higher education (CI: 0.35) and those living in Lima (CI: 0.03) had less inequality in visual examinations (Figure 2).

Moreover, older adults with cataracts but no other health conditions showed higher inequality in receiving eye examinations (CI: -0.11 and ECI: -0.12). While inequality was higher among adults with cataracts and no visual assessment, it was higher among those with other comorbidities such as overweight or obesity (CI: -0.63) or diabetes mellitus (CI: -0.59), as shown in Figure 1B. Also, the proportion of older adults with cataracts increased from 2013 (24.8; 95%CI: 19.6 to 31.0) to 2023 (26.4; 95%CI: 23.7 to 29.3). The percentage of people who had an eye exam stayed the same between 19.6% (95%CI: 17.2 to 22.0) and 27.0% (95%CI: 23.8 to 30.1), but there was less inequality in eye exams from 2013 (ECI: 0.15) to 2020 (ECI: 0.07) and even more in 2023 (ECI: 0.12), as shown in Figure 3.

On the other hand, in terms of geographical distribution at the national level, a considerable variation in older adults with cataracts was observed in regions such as Cajamarca (13.8%) and Arequipa (32.4%). A lot of adults in this group had their eyes checked, but the coverage varied a lot between places like Huancavelica (68.3% of the population) and the constitutional

province of Callao (96.9%). There were also big differences in the visual assessment for older adults with cataracts was spread out across the country (Figure 4). For instance, variations were observed between regions like Tumbes (ECI: 0.06) or Cusco (ECI: 0.29) and Ancash (ECI: 0.29).

DISCUSSION

In this study, we evaluated inequalities in the visual assessment of older Peruvian adults with cataracts from 2013 to 2023. We found that those older adults living in rural areas experience greater disparities in receiving visual assessments, a gap that only increases when seeking surgery for cataract detection (35). Challenges such as limited access to healthcare facilities, irregular screening practices, and financial barriers worsen the disparities in timely diagnosis and treatment for eye conditions (36-40). In addition, the scarcity of ophthalmologists in Peru, with only 39.6 per million inhabitants, compared to countries like Argentina (103.6), Brazil (67.4), and Chile (49.8), perpetuates these inequalities (41,42).

Inequalities in the ophthalmological assessment of older adults with cataracts may be due to differences in waiting times for surgery, which are longer for women and adults with low educational attainment (43-45). This is consistent with studies indicating that older adults from disadvantaged socioeconomic backgrounds have reduced access to essential eye care services, leading to lower utilization rates (46). Therefore, the absence of visual care in the community restricts the availability of vision screening for the population, especially when additional costs are incurred due to the absence of ophthalmological screening covered by national health insurance (47,48).

In 2019, 16.6% of adults aged 50 years and older in Peru reported a diagnosis of cataract, which is lower than the estimated figures for Peruvian older adults with cataract between 2013 and 2023 (49). This figure is worrying given that cataracts account for 58.0% and 59.3% of cases of blindness and severe visual impairment, respectively, in Peru (40). As a result, older adults with limited education experience greater inequalities in visual assessment due to lower rates of visual examinations and follow-up care for cataract detection (50). This represents also an opportunity for educational interventions for visual health in older adults.

Moreover, older adults with cataracts and other health conditions exhibited fewer disparities in their visual assessments. This is notable given the higher likelihood of cataract development in individuals with diabetes mellitus and arterial hypertension (51). Furthermore, as the incidence of these chronic diseases increases with age, in Peru, between 20% and 35% of adults with diabetes had cataracts (52-54). Thus, routine visual assessment of patients with metabolic diseases is crucial from the first level of healthcare (55,56). Routine evaluations could prevent the development of cataracts or other visual diseases.

On the other hand, the COVID-19 pandemic reduced ophthalmological care and the number of elective cataract surgeries (57,58). In Peru, for instance, the impact of the pandemic increased inequalities in eye care (59). Despite the containment of the disease spread, the stagnation of eye health indicators at levels below those before the pandemic poses ongoing challenges for eye care in Peru (60). It is therefore crucial to develop strategies to expand screening, diagnosis, and treatment of eye health problems, as in Peru, the guidelines for managing this disease do not consider the inequalities faced by the population (25,26).

However, there were limitations because the ENDES does not address more aspects related to the development of cataracts in older adults. In addition, the social desirability bias could mediate an overestimation in the number of adults with visual assessments. The years in which the COVID-19 pandemic affected Peru could also modify the precision of the estimates because the form of data collection in the ENDES was modified to virtual platforms. Furthermore, it is unclear what level of understanding these adults have regarding the significance of visual evaluation, their practices for preventing eye health issues, and their responses when dealing with cataracts.

In conclusion, older adults with cataracts living in rural areas or outside Lima and having a lower educational level experienced greater disparities in vision assessments. These results underscore the critical importance of rectifying these disparities to guarantee appropriate eye care and advocate for tailored strategies to enhance the equity of vision screening among vulnerable populations, like older adults. It is vital to tackle these discrepancies in accessing eye care services to guarantee that every older adult, irrespective of their socioeconomic status or location, has equitable access to vision assessments and treatment.
