41 Abstract

- 42 Aims: To explore health patterns in female professional football players in the
- 43 domains of gynaecological health patterns, contraceptive use, body perception and
- 44 motherhood experiences, including return to play after childbirth.
- 45 **Methods**: An online questionnaire was emailed to active female professional football
- 46 players via email. Participants were asked about their menstrual cycle, contraception
- 47 use and motherhood. Validated questionnaires were used to assess body
- 48 dissatisfaction (BD) and drive for thinness (DT).
- 49 **Results**: A total of 74 female professional football players were enrolled. The mean
- age at menarche was 13.5 years, average cycle length of 26 days and a bleeding

51	period of 5 days. Cycle irregularities were experienced by 30% of participants, and
52	menstrual symptoms by 74%. Half of the participants used contraceptives, with 60%
53	using hormonal contraceptives, primarily oral contraceptive pills (38%), followed by
54	implants (20%). Participants had a normal BD score, but a higher-than-expected DT
55	score. The motherhood rate was low (1%), with normal conception, vaginal delivery,
56	return to training after 6 weeks, and return to competition after 12 weeks.
57	Conclusion: Cycle irregularities are common in female professional football players,
58	with a significant number of cycle-related symptoms. The majority on contraceptives
59	preferred hormonal contraceptives, especially oral contraceptive pills (OCP) followed
60	by implants, reflecting trends seen in elite athletes gynaecological health. While body
61	satisfaction scores were normal, there was an unexpectedly high drive-for-thinness
62	score, similar to that observed in lean or weight-category sports. The rate of
63	motherhood was low, consistent with previous findings in professional football
64	players.

70	Data availability statement :
71	All data relevant to the study are included in the article.

72

What is already known on this topic

 Elite female athletes have unique challenges related to their menstrual cycle and symptoms.

- Elite athletes use mostly hormonal contraceptives, predominantly the OCP.
- They often have to choose between professional sports and motherhood.

What this study adds

Our findings show some similarities to other to other elite female athletes:

- 30% have menstrual irregularities.
- 74% have negative menstrual symptoms.
- Motherhood is low.
- Our participants have a high drive for thinness.

How this study might affect research, practice or policy

 This descriptive study is a basis for more prospective and epidemiological research in this cohort that has been established.

 More research will be stimulated in the domains of menstrual symptoms and coping strategies, choice of contraception and motherhood.

 This study should also stimulate communications regarding player contracts and maternity benefits, and include after career support for female professional football players.

73

74

75 INTRODUCTION

76

In recent years, there has been an increase in female participation in sports. Menstrual irregularities, delayed menarche, secondary amenorrhoea and disordered eating (DE) are common amongst female athletes and have been associated with disadvantages in the sporting career, as well as shortening the sporting career of endurance athletes.¹ The menstrual cycle is an integral part of female athletes, and some earlier research suggested that early menarche (below age 12 years) has been

associated with a higher risk of breast cancer due to the early onset of ovulatory
 cycles.²

85

Several surveys have investigated contraceptive use, including the methods chosen and the reasons behind their use.³⁻⁴ These surveys showed that more than 50% of their participants were not on contraceptives at all,⁴ and those who were on contraceptives predominantly used oral contraceptive pills (OCP).³

90

Motherhood experiences (ME) have unique challenges for female athletes, as highlighted in the article 'We are not superhuman, we're human.'⁵ Some of the concerns raised by athletes included: 'training a new body' postpartum; safe return to training; breastfeeding and exercise; and managing time between sports and motherhood. These athletes emphasised the need to develop best practices and secure funding for a safe return to play (RTP).⁵⁻⁶

97

98 Planned and well-structured physical activity under the guidance of an obstetrician-99 gynaecologist during and after pregnancy has been shown to benefit both physical 100 and mental well-being. These benefits include a decrease in gestational diabetes, 101 caesarean and operative vaginal deliveries, and a shorter post-partum recovery 102 time.⁷

103

Several surveys highlighted the difficult choice between motherhood and elite sports participation, the need for careful planning of pregnancy and fertility,⁸ concerns about pregnancy disclosures and fear of discrimination, challenges in training the pregnant body safely, and the lack of a supportive network and funding during the pre- and post-natal periods.⁵

109

These interviews suggest that fewer than 50% of female professional football players have employment contracts comparable to those of their male counterparts. This lack of contractual security places female footballers at a disadvantage because they struggle to sustain themselves financially if they get injured or decide to start a family.⁸

115

Based on the considerations mentioned above, this study aimed to achieve two primary objectives: 1) To explore gynaecological health patterns in female professional football players, including the menstrual cycle, menstrual symptoms, contraceptive use and body perception; 2) To examine motherhood experiences, including methods of conception and delivery, and return-to-play/return to competition after childbirth.

122

123 **METHODS**

124

125 **Study designs and ethical considerations**

An observational prospective cohort study over a follow-up period of six months was conducted using the Strengthening the Reporting of Observational Studies in Epidemiology statement in order to guarantee the quality of reporting.⁹ The Medical Ethics Review Committee of the Amsterdam University Medical Centers (Amsterdam UMC, location AMC) provided ethical approval for the study (Drake Football Study: NL69852.018.19 | W19_171#B202169). The study was conducted in accordance with the Declaration of Helsinki (2013).

133

134 Setting

Participants from English and French speaking countries were recruited by Football
Players Worldwide (FIFPRO) and affiliated national unions via email from September
202 to May 2021. Initial data collection was completed in December 2022, and
participants will be followed at 6 months' intervals over a period of 10 years..

139

140 **Participant selection**

141 The study population consisted of female professional footballers. Inclusion criteria 142 were: (a) being a professional footballer, (b) being female, (c) being able to read and 143 comprehend texts in English or French. In our study, the definition for a professional 144 footballer was that she (i) trains to improve performance, (ii) competes in the highest 145 or second highest national league, and (iii) has football training and competition as a 146 major activity (way of living) or focus of personal interest, devoting several hours in all or most of the days for these activities, and exceeding the time allocated to other 147 148 types of professional or leisure activities. Sample size calculation indicated that at 149 least 40 participants were needed to reach a power of 80% (confidence interval (CI) 150 of 95% and absolute precision of 7%) under the assumption of an anticipated population proportion (prevalence) of 5%.¹⁰ 151

152

153 **Dependent variables**

Various female-specific variables were collected through single questions related to (history of) pregnancy, fertility (e.g., in vitro fertilisation, sperm donation), miscarriage, adoption, date of menarche, menstrual cycles, (history of) amenorrhoea, use of contraceptive measures (e.g., oral, implant), experiences related to motherhood (e.g.,

vaginal delivery, caesarean delivery), return to training (RTT)/return to competition(RTC) and body perception.

160

161 Body perception was measured by using the body dissatisfaction (BD) and drive for 162 thinness (DT) scores. These were measured with two of the 12 primary scales of the 163 Eating Disorder Inventory (EDI-3).¹¹ This validated tool ensures a reliable interpretation of the psychometric test.¹² BD relates to the disapproval of the overall 164 165 shape of one's body and the size of specific body regions of particular concern. DT 166 consists of perceptual, behavioral, and attitudinal parts and is probably triggered 167 when there is a discrepancy between actual and ideal body weight that exceeds the 168 specific idealised preference of cultural thinness and involves body image dissatisfaction.¹¹ 169

170 The supplementary material presents all the questions in the survey. Annexure A.

171

172 **Descriptive variables**

Participant characteristics and several descriptive variables (e.g., age, height, body mass index (BMI), player position, and stress fractures) were collected using an electronic questionnaire.

176

177 **Procedures and data storage**

A baseline and a follow-up electronic questionnaire were set up in English and French (CastorEDC, CIWIT B.V, Amsterdam, the Netherlands), including all study outcome measures. In addition, the following descriptive variables were added to the baseline questionnaire: level of education, parallel activity (e.g., study, work), level of football, number of seasons as a professional footballer, history of hospitalisation,

183 history of eating disorders, and smoking status. Information about the study was sent 184 per email to potential participants by FIFPRO and affiliated national unions, and 185 procedures were hidden from the principal researcher for privacy reasons. If 186 interested in the study, all participants gave informed consent and received access to 187 the baseline questionnaire. The follow-up questionnaire was sent six months later. 188 Each questionnaire took about 15 minutes to complete. The responses to the 189 questionnaires were coded and made anonymous for reasons of privacy and 190 confidentiality. The electronic questionnaires were saved automatically on a secured 191 electronic server that only the principal researcher could access. Players participated 192 voluntarily in the study and were not rewarded for their participation.

193

194 Statistical analyses

The Statistical software, R (version 4.2.1; http://www.r-project.org) was used to perform all data analyses. Descriptive analyses (mean, standard deviation (SD), frequency and proportions) were performed for all variables included in the study, including Body Mass Index (BMI) calculated as a ratio of weight/height squared.¹³

199

200 **RESULTS**

201

202 **Participant characteristics**

203 Seventy-four women athletes were recruited, with a mean age of 25 years and an 204 average BMI of 22. Table 1 depicts demographics, football characteristics, career 205 level and employment status. The majority of our participants were defenders (34%), 206 followed by forwards (30%), midfielders (23%) and goalkeepers (14%). Most

- 207 participants were did not have another paid job (70%), and most (87%) participated
- 208 at the highest national level.

209

210 Table 1: Demographics, football characteristics, employment status and career level

Demographics	All Participants (n = 74)	
Age (yrs) mean (SD)		24.95 (2.69)
Height (cm) mean (SD)		168.39 (5.38)
Weight (kg) mean (SD)		62.81 (5.4)
BMI (kg/m²) mean (SD)		22.14 (1.47)

Body dissatisfaction Mean (SD)		4.88 (5.08)
Drive for thinness Mean (SD)		3.59 (5.04)

220 SD = standard deviation; BD = Body dissatisfaction; DT = Drive for thinness

221

222 Motherhood experiences and RTT/RTC

223 Only one (1.4%) of the 74 participants had two children, both conceived naturally and

delivered vaginally. Her RTT was 6 weeks, and RTC 12 weeks on both occasions.

225

226 **DISCUSSION**

227

The findings from this study provide a baseline of active female professional football players' gynaecological health behaviours, whilst most studies reported on retired elite athletes,¹⁴ or elite athletes from other sports.¹⁵⁻¹⁶ Our findings were that:1)

231 hormonal contraceptives, particularly the oral contraceptive pill, were the most

commonly used, 2) cycle irregularities were common, 3) most participants
experienced cycle-related pain, and 4) motherhood experiences were rare, at just
1%.

235

236 Menstrual cycle

237 Mernache is the average age at which menstrual bleeding starts in young females, 238 and usually, this is between the ages of 12-13 years. It has been reported that the 239 onset of menarche is usually delayed in athletes participating in lean sports, but no variations were noted between individual and team sports.⁴ Our participants had a 240 mean menarche age of 13.5 years, comparable to other studies on elite athletes.¹⁴ 241 242 Our results showed that 30% of our participants had cycle irregularities. Our findings 243 indicate a higher prevalence of cycle irregularities compared to Swiss elite athletes from various sports, where approximately 15% reported such issues.⁴ However, our 244 results are lower than those for elite athletes in Denmark¹⁷ and the United Kingdom,¹⁵ 245 246 where 51% of athletes reported cycle irregularities. Retired semi- and professional 247 football players reported a 40% prevalence of menstrual irregularities, with 22% experiencing amenorrhoea lasting longer than 3 months.¹⁴ 248

249

Menstrual pain was reported by 74% of our participants. Symptoms were present before the bleeding period in 20% and during the menstrual phase in 54% of participants. This is comparable to the findings in a UK survey where 77% of elite athletes reported menstrual pain.¹⁵ Elite rugby players reported menstrual pain in 93% of participants,¹⁶ and 84% of elite Denmark athletes reported negative symptoms related to their menstrual cycle.¹⁷

256

A study among elite rugby and football players on premenstrual pain and coping strategies suggested a model including avoiding harm, awareness and acceptance, adjusting energy, self-care, and communication to help maintain well-being and physical activity during this period.¹⁸ Our study was not designed to investigate coping strategies, and this will require further investigation.

262

Several studies have shown that athletes believe that their performance declines when they experience menstrual-related symptoms.^{16-17,19-20} A survey of sub-elite female football players showed a reduction in endurance performance during the menstrual phase,²¹ while elite Australian football players reported higher perceived fatigue during this period.²² Our study did not investigate the impact of the menstrual cycle on exercise performance, highlighting the need for future research to address this gap in the literature on female professional football players.

270

271 Contraceptive use

272 Our findings confirm that 50% of our participants were on contraceptives, mainly HCs 273 (60%), predominantly the OCP (38%), followed by implants (20%) and injectable 274 contraception (2%). These findings are consistent with findings amongst other elite 275 athletes, with 50% on HCs, predominantly the OCP (68.%), followed by the implants (13%), injection (4%) and intra-uterine devices (3%).¹⁵ In elite Australian football 276 codes, HCs use was 33%, with 81% on the OCP.³ A survey on Swiss players 277 reported that 46% were on contraception, and 26% used the OCP,⁴ and a study on 278 Danish players reported 57% use of HCs and all of them on OCP.¹⁷ Amongst retired 279 280 professional football players from the United States (US), the trend was similar, 281 although more participants (64.5%) had used HCs, predominantly the OCP

(94.5%).¹⁴ Some of our participants reported the use of more than one contraceptive
method. Our study was not designed to investigate reasons for the use of different
methods and what 'other methods' were used. Further research is warranted on this
topic.

286

287 BD and DT

288 Our participants had a normal BD score of 5. This finding aligns with findings in 289 federated Spanish amateur football players, who also reported high positive body images and a normal BD score of 5.²³ We are not aware of other similar studies in 290 291 female professional football players. A systematic review and meta analysis across 292 different sports and genders highlighted the importance of sports participation in 293 fostering positive body image. The study found that female athletes had higher BD 294 scores than males, normal-weight athletes had higher BD scores than underweight 295 ones, and compared to non-athletes, female athletes tend to have a higher body image perception.²⁴ 296

297

298 Our participants had a high mean DT of 4, which was not expected in football. Higher DT scores are common in aesthetic and weight category sports.²⁵ We are not aware 299 300 of other comparable studies in female professional football players. High DT has 301 been correlated to susceptibility to musculoskeletal injuries due to low energy 302 availability in the National Collegiate Athletic Association (NCAA) Division II female athletes and higher time loss from training.²⁶ In this NCAA survey, 82% of 303 304 participants sustained musculoskeletal injuries in-season. The mean number of 305 injuries/training days loss was higher in the high DT group (over 2.0 ± 0.3), with 9.8

306 (2.6) days loss from training, whilst the low DT group (under 2.0 \pm 0.3) had 6.9 (2.6)

307 days loss.²⁶

308

309 We found that 70% of our participants did not have another paid job, 58% were not 310 studying, and 13 (17.6%) smoked. These factors, combined with a high DT, warrant 311 further monitoring of these athletes to promote well-being. As confirmed in one study, 312 high DT is a risk factor for the development of ED, and personal risk factors for DT 313 include perfectionism, low self-esteem in sport, unemployment, and not studying²⁷ and has been linked to tendencies towards smoking.²⁸ Although ED was found to be 314 higher in non-athletes compared to elite female football players,²⁹ the combination of 315 316 risk factors for ED and susceptibility to musculoskeletal injuries warrant further 317 monitoring and research.

318

319 Motherhood experiences

320 In our study, only one participant (1%) reported having had two pregnancies and she 321 conceived naturally. Both children were delivered vaginally, and she returned to 322 training and competition 6 and 12 weeks post-partum, respectively. The US study 323 reported that 50% of the participants reported trying to fall pregnant, with a 94% 324 success rate, mostly by intra-uterine insemination (51%), medication (49%) and invitro fertilisation (43%).¹⁴ Our sample is too small to compare. Still, we could assume 325 326 that pregnancy during a professional football career remains challenging as players 327 might be afraid to potentially jeopardise their career due to motherhood.

328

329 It has been shown that some professional athletes opt to choose between being 330 mothers and continuing to participate in sports,⁸ but similar to our study, other

athletes have successfully fallen pregnant and managed to RTT/RTC earlier than
non-athletes.³⁰ Although early RTT has been associated with an increased risk for
stress fractures, high BD and high DT,³⁰ this has not been confirmed in our study.
FIFPRO reported in 2017 that only 2% of female professional football players were
mothers, and almost 45% expressed that they would have to leave the game early to
start a family.³¹ Our study's low percentage of motherhood is comparable to the

338 FIFPRO findings. The choice between motherhood and professional football was not

canvassed in our study, but it will form a basis for future research.

340

341 Strengths and Limitations

The strength of our study lies in its pioneering focus on the gynaecological health patterns and motherhood experiences of active female professional football players. Although our study is descriptive, our research provides a valuable cohort for future prospective and epidemiological studies. We hope this study will inspire further research in the realm of female professional football players.

347

Our study has several limitations, including the small sample size and the lack of investigations into participants' perceptions of exercise performance during the menstrual cycle, their coping strategies for menstrual symptoms, reasons for contraceptive choices, and their views on balancing motherhood with professional sport. We did not investigate any correlation between injuries and the menstrual cycle. Our findings on motherhood experiences are also limited by the low number of participants. Further research is needed to address these gaps.

355

356 Implications

357 Women's football is growing globally, and factors unique to women may affect their 358 performance and/or shorten their sporting career. This study highlights the 359 challenges faced by these athletes, including menstrual cycle-related symptoms that 360 may affect performance and sporting career, and the importance of specialised 361 gynaecological care for female elite athletes. Healthcare practitioners, coaches and 362 team managers working with elite female athletes should be trained to improve 363 communication, guide athletes on general trends in gynaecological health patterns, 364 optimise well-being, and advise on safe RTT and RTC after motherhood.

365

More research, such as athlete perception of menstrual cycle effects on performance, coping strategies when experiencing menstrual pain, choice and reasons for use of contraceptives, and choice of sports versus motherhood, is needed in female professional football players.

370

371 CONCLUSION

372 Cycle irregularities are common in female professional football players, with a

373 significant number of cycle-related symptoms. The majority of those using

374 contraceptives preferred hormonal contraceptives, predominantly oral contraceptive

375 pills followed by implants, reflecting trends similar to other female elite athletes. While

body satisfaction scores were normal, there was an unexpectantly high DT score,

377 similar to that observed in lean or weight-category sports. The rate of motherhood

378 was low, consistent with previous findings in professional football players.

FUNDING

The study received seed funding from the Drake Foundation located in London (UK) and financial support from Mehilainen NEO Hospital located in Turku (Finland), from Sports Hospital Mehilainen located in Helsinki (Finland) and from Nea International bv. located in Maastricht (the Netherlands).

WORD COUNT

Abstract: 242 Main Body excluding tables: 2728 Number of tables: 2

Gynaecological health patterns and motherhood experiences of female professional football players © 2024 by Dr DA Ramagole is licensed under CC BY-NC-ND 4.0

	Item No	Recommendation	Page No
Title and abstract	1	(<i>a</i>) Indicate the study's design with a commonly used term in the title or the abstract	6
		(b) Provide in the abstract an informative and balanced summary of what	2-3
		was done and what was found	23
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-5
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	6
Setting	5	Describe the setting, locations, and relevant dates, including periods of	6
Security	U	recruitment, exposure, follow-up, and data collection	Ũ
Participants	6	(a) Cohort study—Give the eligibility criteria, and the sources and methods	6
I		of selection of participants. Describe methods of follow-up	-
		<i>Case-control study</i> —Give the eligibility criteria, and the sources and	
		methods of case ascertainment and control selection. Give the rationale for	
		the choice of cases and controls	
		Cross-sectional study—Give the eligibility criteria, and the sources and	
		methods of selection of participants	
		(b) Cohort study—For matched studies, give matching criteria and number	6-7
		of exposed and unexposed	
		Case-control study-For matched studies, give matching criteria and the	
		number of controls per case	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders,	7
		and effect modifiers. Give diagnostic criteria, if applicable	
Data sources/	8*	For each variable of interest, give sources of data and details of methods of	7
measurement		assessment (measurement). Describe comparability of assessment methods if	
		there is more than one group	
Bias	9	Describe any efforts to address potential sources of bias	N/A
Study size	10	Explain how the study size was arrived at	6-7
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If	N/A
		applicable, describe which groupings were chosen and why	
Statistical methods	12	(a) Describe all statistical methods, including those used to control for	8
		confounding	
		(b) Describe any methods used to examine subgroups and interactions	N/A
		(c) Explain how missing data were addressed	N/A
		(<i>d</i>) <i>Cohort study</i> —If applicable, explain how loss to follow-up was addressed	N/A
		<i>Case-control study</i> —If applicable, explain how matching of cases and controls was addressed	
		Cross-sectional study—If applicable describe analytical methods taking	
		cross scontrunt sinury in approacte, accounte anarytical methods taking	1

STROBE Statement-checklist of items that should be included in reports of observational studies

Continued on next page

N/A

account of sampling strategy

(e) Describe any sensitivity analyses

Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	9
		(b) Give reasons for non-participation at each stage	N/A
		(c) Consider use of a flow diagram	N/A
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	9
		(b) Indicate number of participants with missing data for each variable of interest	N/A
		(c) <i>Cohort study</i> —Summarise follow-up time (eg, average and total amount)	6
Outcome data	15*	Cohort study—Report numbers of outcome events or summary measures over time	10
		Case-control study—Report numbers in each exposure category, or summary measures of exposure	
		Cross-sectional study—Report numbers of outcome events or summary measures	10
Main results	16	(<i>a</i>) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	N/A
		adjusted for and why they were included	NI/A
		(<i>c</i>) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	N/A N/A
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	N/A
Discussion			
Key results	18	Summarise key results with reference to study objectives	10- 15
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	15- 16
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	16
Generalisability	21	Discuss the generalisability (external validity) of the study results	16- 17
Other informati	ion		
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	17

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). Information on the STROBE Initiative is available at www.strobe-statement.org.

Tables

Table 1: Demographics, football characteristics, employment status and career level

Demographics	All Participants (n = 74)	
Age (yrs)		24.05 (2.60)
mean (SD)		24.95 (2.69)
Height (cm)		168 30 (5 38)
mean (SD)		100.39 (0.30)
Weight (kg)		62.81 (5.4)
mean (SD)		02.01 (3.4)
BMI (kg/m²)		22 14 (1 47)
mean (SD)		22.14 (1.47)
Stress fracture	es	11 (15)
n (%)		11 (13)
Low bone der	nsity	1 (1 35)
n (%)		1 (1.55)
Other characteristics		
Field Postion	defender	25 (34%)
n (%)	forward	22 (30%)
	midfield	17 (23%)
	goalkeeper	10 (13%)
Number of seasons as		
a professional player		5.74 (3.12)
Mean (SD)		
Employed	yes	22 (30%)
Level of Football	highest national level	64 (87%)
n (%)	second highest national level	6 (8 %)
<u> </u>	other	4 (5%)

Yrs = years; SD = standard deviation; cm = centimetres; kg = kilograms; BMI = Body Mass Index

Table 2: Gynaecological health patterns, BD and DT

Variable	Characteristics	All Participants (n = 74)
Age of Menstruation (yrs)		40.47 (4.0)
Mean (SD)		13.47 (1.3)
Duration of menstruation cycle (days Mean (SD)		25.81 (13.09)
Duration of menstrual bleeding period (days) Mean (SD)		5.16 (3.42)
Description of menstruation cycle	regular	52 (70%)
	irregular	15 (20%)
11 (70)	very irregular	7 (10%)
Pain during menstruation cycle	during bleeding period	40 (54%)
	none	19 (26%)
11 (70)	before bleeding period	15 (20%)
	none	37 (50%)
	pill	14 (38%)
	condom	12 (32%)
	other	8 (22%)
Contraception Methods n (%)	implant	7 (20%)
	hormone replacement	4 (10%)
	injection	1 (2%)
Body dissatisfaction		4.99 (5.09)
Mean (SD)		4.00 (0.00 <i>)</i>
Drive for thinness		3 50 (5 04)
Mean (SD)		0.09 (0.0 4)

SD = standard deviation; BD = Body dissatisfaction; DT = Drive for thinness

What is your age? [Number] How tall are you (cm)? [Number] How much do you weigh (kg)? [Number] What is your percentage of body fat (%)? [Number] What is the highest level of education you have completed? [No school completed; Nursery/Elementary school; High school; Vocational/technical school; College, university or equivalent] Apart from your professional football career, are you currently studying? [Yes: No] If yes, how many hours per week on average do you study? Apart from your professional football career, do you have currently another paid job? [Yes: No] If yes, what other kind of (paid) work do you do? If yes, how many hours per week on average do you work (apart from your professional football career)? What is your position on the field? [Goalkeeper: Defender: Midfield: Forward] At what level do you play? [Highest national level/league; Second highest national level/league; Other] For how many seasons are you a professional footballer? [Number] In the past few years, were you admitted to an hospital? If yes, why? Have you been diagnosed with a mental health disorder (e.g., depression, anxiety, insomnia)? [Yes; No; I don't know] If yes, which mental health disorder(s)? How many cigarettes (approx.) have you smoked in your entire life? [Number] How many days have you smoked cigarettes during the past 30 days? [Number] Have you been pregnant? [Yes; No] IF YES How many times have you been pregnant? [Number] IF YES How did you get pregnant? [Intercourse: Insemination with partner's sperm; Insemination with sperm donation; I rather not tell] How many miscarriages did you have? [Number] Body dissatisfaction (validated EDI-3 subscale) I think that my stomach is too big. I think that my thighs are too large. I think that my stomach is just the right size. I feel satisfied with the shape of my body. I like the shape of my buttocks. I think that my hips are too big. I think that my thighs are just the right size. I think that my buttocks are too large. I think that my hips are just the right size. [Always; Usually; Often; Sometimes; Rarely; Never] Drive for thinness (validated EDI-3 subscale) I eat sweets and carbohydrates without feeling nervous. I think about dieting. I feel extremely guilty after overeating. I am terrified of gaining weight.

I exaggerate or magnify the importance of weight. I am preoccupied with the desire to be thinner. If I gain a pound, I worry that I will keep gaining. [Always; Usually; Often; Sometimes: Rarely; Never] At about what age did you begin to menstruate? [Age] What is the average duration of your menstrual cycle (i.e., average number of days between the first day of your menstrual cycles)? [Number of days] What is the average duration of your menstrual bleeding period? [Number of davs] How would you describe your menstrual cycle? [Regular; Irregular, Very irregular] Since your first menstrual cycle, did your menstrual bleeding period stop for three or more consecutive months (for other reasons than hormonal contraception)? [No: Yes] Do you generally experience pain during your menstrual cycle? [No: Yes, before a bleeding period; Yes, during a bleeding period; Yes, after a bleeding period] Are you currently using contraceptives? [No; Yes, cap; Yes, pill; Yes, condom; Yes, contraceptive implant; Yes, contraceptive injection; Yes, contraceptive patch: Yes, diaphragm: Yes, female condom: Yes, namely...] Are you currently using hormone replacement? [No; Yes] Are you a mother? [No: Yes] If YES How many children do you have? [Number] If YES How did you give birth? [Vaginal delivery; Caesarean delivery; Adoption] If DELIVERY How long did it take before you returned to training? Child 1 Child 2 Child X [Number of weeks] If DELIVERY How long did it take before you returned to competitive matches? [Number of weeks] Have you ever had a stress fracture? [No; Yes] If YES please indicate when it occurred and what bone(s). Have you even been told you have low bone density (e.g., osteopenia or osteoporosis)? [No; Yes] How many severe injuries in your LEFT hip have you had so far as professional footballer? [Number]

How many severe injuries in your RIGHT hip have you had so far as professional footballer? [Number]

How many severe injuries in your LEFT knee have you had so far as professional footballer? [Number]

How many severe injuries in your RIGHT knee have you had so far as professional footballer? [Number]

How many severe injuries in your LEFT ankle have you had so far as professional footballer? [Number]

How many severe injuries in your RIGHT ankle have you had so far as professional footballer? [Number]
