Supplementary Table 1. Variant of concern detection overall and by epidemiological week, ≥18-year-old study participants, British Columbia and Quebec, Canada

In variant-specific analyses, cases were categorized as Alpha, Gamma, or Delta variants of concern (VOC)^{1,2}. In both provinces, the methods and sampling frame for genetic characterization of viruses evolved in response to changing epidemic patterns, case load and laboratory capacity. In British Columbia (BC), genetic characterization of all case viruses was attempted by whole genome sequencing (WGS) between weeks 22 and 35 as previously described,^{3,4,5,6} but with WGS applied to a subset only (10% random sample in addition to all hospitalized, vaccinated or outbreak-associated cases) between weeks 36-39 when the Delta variant almost solely contributed. In Québec,⁷ between week 22 and week 35, diagnosis of Alpha was foremost by RT-PCR single-nucleotide polymorphism (SNP) screen for signature mutations, with a subset identified by WGS. After week 35, most Alpha diagnoses were by WGS. Detection of Delta by RT-PCR SNP screen was confirmed by WGS until week 24 and thereafter foremost by RT-PCR screen alone with a subset identified by WGS. The Gamma variant was detected in Quebec by WGS.

As shown in the table below, in each province about two-thirds of case viruses overall in the current study were genetically characterized. In BC, 91% of all participant case viruses were genetically characterized between weeks 22-35 with Alpha and Gamma variants comprising an approximately equal share (49% and 43%, respectively) between weeks 22-25, but <25% combined between weeks 26-30 and <1% between weeks 31-35 when Delta represented 77% and 99% of all characterized viruses, respectively.

Although just 30% of participant case viruses were characterized in BC between weeks 36-39, Delta comprised virtually all of these. In Quebec, the Alpha variant predominated over Delta in weeks 22-25 (97%) and 26-30 (77%) but with Delta predominating over Alpha from August to October, including weeks 31-35 (89%) and 36-39 (99%). Quebec did not detect any Gamma or Beta variants and BC detected a single Beta variant [not displayed below] among participant cases during the analysis period.

VE=vaccine effectiveness; 95%CI=95% confidence interval; NE=Not estimable

¹ Unless otherwise specified, all VE estimates adjusted for sex (male, female); individual epidemiological week of the analysis period (weeks 22-39, categorical); and region of the province (5 in each province).² In Quebec, adjusted VE estimates against hospitalization in 18-49-year-olds were adjusted for calendar time bi-weekly owing to sample size.³ Among those ≥ 70 years, VE additionally adjusted for 70-79 and ≥ 80 years in both provinces.⁴ In Quebec, adjusted VE estimates against hospitalization in ≥ 70 -year-olds were adjusted for calendar time tri-weekly owing to sample size.⁵ In Quebec, adjusted VE estimates against hospitalization in ≥ 80 -year-olds were adjusted for calendar time tri-weekly owing to sample size.

VE=vaccine effectiveness; 95%CI=95% confidence interval; NE=Not estimable

¹ Unless otherwise specified, all VE estimates adjusted for age group (18-49, 50-69, 70-79, ≥ 80 years); sex (male, female); individual epidemiological week of the analysis period (weeks 22-39, categorical); and region of the province (5 in each province).

² In Quebec, VE against hospitalizations due to Delta variant assessed only between weeks 31-39 because no hospitalized Delta variant cases were identified prior to that period.

³ In BC, adjusted VE against Alpha infections adjusted for calendar time as individual epidemiological weeks 22-35, but regrouping weeks 36-39 together owing to sample size considerations.

⁴ In BC, adjusted VE against Alpha hospitalizations adjusted for calendar time as individual epidemiological week 22-33, regrouping weeks 34-39 owing to sample size considerations.

⁵ In Quebec, VE against Alpha hospitalizations assessed only between weeks 23-38, and adjusted for calendar time by four epidemiological week periods.

VE=vaccine effectiveness; 95%CI=95% confidence interval; NE=Not estimable

¹ Unless otherwise specified, all VE estimates adjusted for age group (70-79, ≥ 80 years); sex (male, female); individual epidemiological week of the analysis period (weeks 22-39, categorical); and region of the province (5 in each province).

² In Quebec, adjusted VE estimates against hospitalization in ≥ 70 -year-olds were adjusted for calendar time tri-weekly owing to sample size.
