

Supplemental Figure 1

a

b

Supplemental Figure 1. Silhouette results for each of the omics data

independently and the integrated multi-omics data. The silhouette method was performed on both cohorts with the number of clusters (k) ranging from 2 to 10. The silhouette method is used to evaluate how well each patient lies within their assigned cluster compared to its neighbour cluster. A high silhouette width value indicates the samples are well matched to their clusters. The silhouette plots of the optimal assignment results (the

highest average silhouette width) for each data type were also shown to reflect the silhouette width of each individual. **(a)** The silhouette method was performed on the DCS cohort consisting of 589 T2D patients. **(b)** The silhouette method was performed on the GoDARTS cohort consisting of 545 T2D patients.

Supplemental Figure 2

Supplemental Figure 2. Multi-omics clustering results were validated by bootstrapping (n=1000 iterations) test. The simulated models were iterated 1000 times to record the frequency of achieving a model with an equal or greater mean local cluster coefficient than the study model. For the simulated data, the same parameters were used and the number of clusters is set to correspond to the number of clusters in the study model. The dash lines indicate the local coefficient of the study models.

Supplemental Figure 3

a.

b.

ESM Figure 3. Clinical features of multi-omics clusters in both DCS and GoDARTS

cohorts. Distributions of clinical measurements at baseline in DCS (a) and GoDARTS

(b) for multi-omics cluster #1 and cluster #2. SBP=systolic blood pressure.

DBP=diastolic blood pressure. HbA1C=Hemoglobin A1C. GAD1=Glutamic Acid

Decarboxylase 1. SIRD= severe insulin-resistant diabetes. CL1=multi-omics cluster #1.

CL2=multi-omics cluster #2. *:P-value<=0.05. **:P-value<=0.01. ***:P-value<=0.001.

Supplemental Figure 4

b.

Supplemental Figure 4. Clinical features of multi-omics clusters and the clinical clusters in both DCS and GoDARTS cohorts. Distributions of clinical measurements at baseline in DCS (a) and GoDARTS (b). CL1= multi-omics cluster #1. CL2= multi- omics cluster #2. MD= mild diabetes. MDH=mild diabetes with high HDL. MOD= mild obesity-related diabetes. SIDD= severely insulin-deficient diabetes. SIRD= severely insulin-resistant diabetes.

Supplemental Figure 5. Features (lipids and proteins) that are strongly associated ($P\text{-value} \leq 0.05$) with SNF clusters in both DCS and GoDARTS cohorts, visualized as heatmaps. Multi-omics clusters were generated from integrated lipidomics and peptidomics. Features association levels with each cluster were assessed by logistic regression and adjusted by gender, BMI and age. Concentrations of each feature were first converted into the $\log(\text{concentration})$ and then normalized in order to investigate the relative expression level of each feature between different clusters (Row Z-score). Heatmap cells were coloured in red/green to represent the relative expression level (red=low, green=high). The federated database does not allow to pull individual sample's data in order to protect the patient's identity. Each vertical line in the heatmap represents 5 different patients' mean values for each feature.

Supplemental Table 1

	DCS	GoDARTS
Clinical measures Pseudo R^2		
Age	0.0057	0.0053
BMI	0.0427	0.0097
C-peptide	0.0836	0.0303
LDL Cholesterol	0.0103	0.1167
HDL Cholesterol	0.0776	0.0717
Triglycerides	0.2589	0.4309
Age+BMI+C-peptide+LDL Cholesterol+ HDL Cholesterol+Triglycerides	0.2993	0.4689

Supplemental Table 1. Pseudo R square of six clinical measurements act as univariate or together as covariates for improvement of the prediction of multi-omics clustering assignments in a logistic regression model. Patients' multi-omics clustering assignments were treated as dependent variables and labelled as 1 or 0 (cluster #1:1, cluster #2:0). Pseudo R square was calculated based on the formula: Pseudo R square = $1 - (\text{deviance} / \text{null deviance})$.
