

Supplementary Figure S2: SFRP4 is more highly induced in samples with inflammatory cells on histopathology compared to those with only sclerosis. Dot plot of SFRP4 gene expression in affected skin compared to unaffected skin. Affected specimens were grouped according to the overall histopathology, identifying specimens with changes that were "sclerotic" (sclerotic changes without significant inflammation), "Scl + peri" (sclerotic changes and perivascular inflammation without significant epidermal changes), and "Scl + epi" (sclerotic changes with necrotic keratinocytes, melanophages, and/or interface dermatitis). Unaffected skin was labeled as "normal."
