

Supplementary:

The data of monkeypox outbreaks are listed in Table A1. The results of predicted monkeypox cases by Bayesian SIR model are also listed in Table A1.

The deterministic SIR model

A deterministic Susceptible-Infected-Recovered (SIR) model was also used for the Monkeypox outbreaks.

Nonlinear ordinary differential equations of the COVID-19 model were used to describe the dynamic changes of each state as follows.

$$\frac{dS(t)}{dt} = -\beta \frac{S(t)}{N} I(t) \quad (1)$$

$$\frac{dI(t)}{dt} = \beta \frac{S(t)}{N} I(t) - \alpha I(t) \quad (2)$$

$$\frac{dR(t)}{dt} = \alpha I(t) \quad (3)$$

Where β denotes the transmission coefficient, overall transmissibility with contact rate; α denotes reciprocal of the infectious period (8.5 days) and it was set to be 0.1176. The formula of deriving the basic reproductive number (R_0) is $\frac{\beta}{\alpha}$. The β and R_0 were obtained after fitting the observed cases

with monkeypox by the simulation of this model by deterministic SEIR model. The assumptions of our deterministic SEIR model are as follows. (1) Homogeneous random mixing population; (2) fixed infectious period. The simulation of the deterministic SEIR model was performed by using the software of MATLAB version 9.30.713579 (MathWorks, USA).

The results of estimated parameters for monkeypox in the global, United States, Spain, Brazil, and United Kingdom are listed in Table A2. The observed cumulative monkeypox cases and simulated cumulated Monkeypox cases on the global, United States, Spain, Brazil, and United Kingdom are shown in Figure A1. The results of simulated monkeypox cases by the deterministic SIR model are listed in Table A3.
