Supplementary Methods

Independent associations from public GWAS

To select lung disease-associated variants for clustering analysis, we mined results from public GWAS of COPD¹, lung function phenotypes² and asthma^{3,4}. Methods to identify independent associations varied across studies. The COPD GWAS¹ revealed 82 independent genome-wide significant loci ($P < 5 \times 10^{-8}$). Secondary signals were then obtained by conditional and joint analysis at each of the 82 loci, adding other 82 secondary variants and resulting in the total number of 164 variants for COPD. The GWAS of four lung function phenotypes², forced expired volume in 1 second (FEV1), forced vital capacity (FVC), FEV1/FVC and peak expiratory flow (PEF), reported 139 independent genome-wide significant loci ($P < 5 \times 10^{-9}$) associated at least with one phenotype. Further follow-up joint analysis of the 139 loci identified 140 additional variants, resulting in a total of 279 lung function variants. Our custom meta-analysis of two asthma GWAS from UK Biobank⁴ and the GABRIEL consortium³ yielded 45 independent variants. It was not enriched for secondary signal at those loci.

Enrichment analysis with FUMA

We used FUMA⁵ SNP2GENE function (<https://fuma.ctglab.nl/snp2gene>) to associate SNPs with protein coding genes based on two criteria, the physical position (in 30kb radius of a gene) and eQTLs (all significant cis-eQTL from GTEx up to a distance of 1Mb). For the latter, we restrained the eQTLs to the one that were found in relevant tissue for the trait under study (COPD, Asthma, lung function), including immune cells, blood vessels, lung, and adipocyte. Note that the FUMA SNP2GENE function requires association p -values. Here we used the minimum p -value reported across the three studied traits. For genes mapped within each clusters, we then performed a functional enrichment for pathways defined in KEGG⁶, GO⁷, BioCarta, Reactome⁸, databases, and the ad hoc *immunologic_signature* gene sets, using the FUMA GENE2FUNC function. For the enrichment p -values, the cluster's gene were compared against a background of protein coding genes.

Supplementary Figures

Figure S1. Distribution of Z-scores for asthma, FEV1 and FEV1/FVC as a function of COPD Z-score across the 377 independent variants

Association Z-score for COPD across 377 independent variants plotted as a function of association Z-score for asthma (a), FEV1 (b) and FEV1/FVC (c). Variants selected from the COPD GWAS are indicated by a black circle. Variants nominally significant with COPD are indicated in orange.

The color encodes the gradient of association Z-scores from positive (blue) to negative (red) between the 482 variants and the 44 traits. Rows and columns were ordered using a hierarchical clustering based on Ward.D2 methods applied to Euclidean distance. The resulting clustering of SNPs is indicated on the right side of the figure.

Figure S3. Alluvial plot illustrating the assignment of variants in the three clusters.

The alluvial plot provides an overview of the assignment of the 164, 279, and 45 variants for COPD, lung function, and asthma, into the clusters 1, 2 and 3. Note that the three clusters included 156, 148 and 78 variants, respectively, with a subset of 106 variants that could not be formally assigned to any cluster.

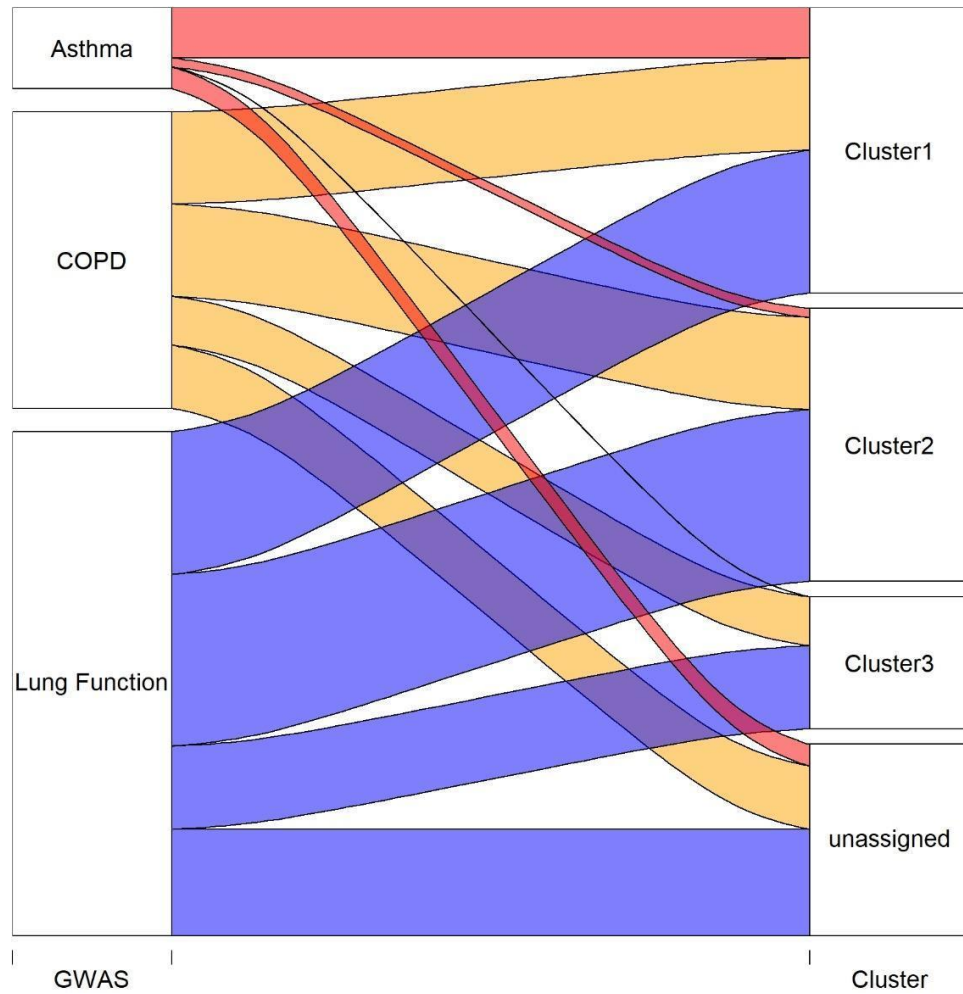

Figure S4. Marginal effect of genetic risk score across COPDgene phenotypes

We plotted the association Zscore for the 61 phenotypes for which at least one GRS reaches the Bonferroni corrected p-value threshold of 7×10^{-5} . The red dash lines indicate the significance p-value threshold. Phenotypes are ordered based on the largest absolute Zscore across the four GRS. Phenotypes for which one of GRS_{1-3} was more associated than GRS_0 are indicated by a star.

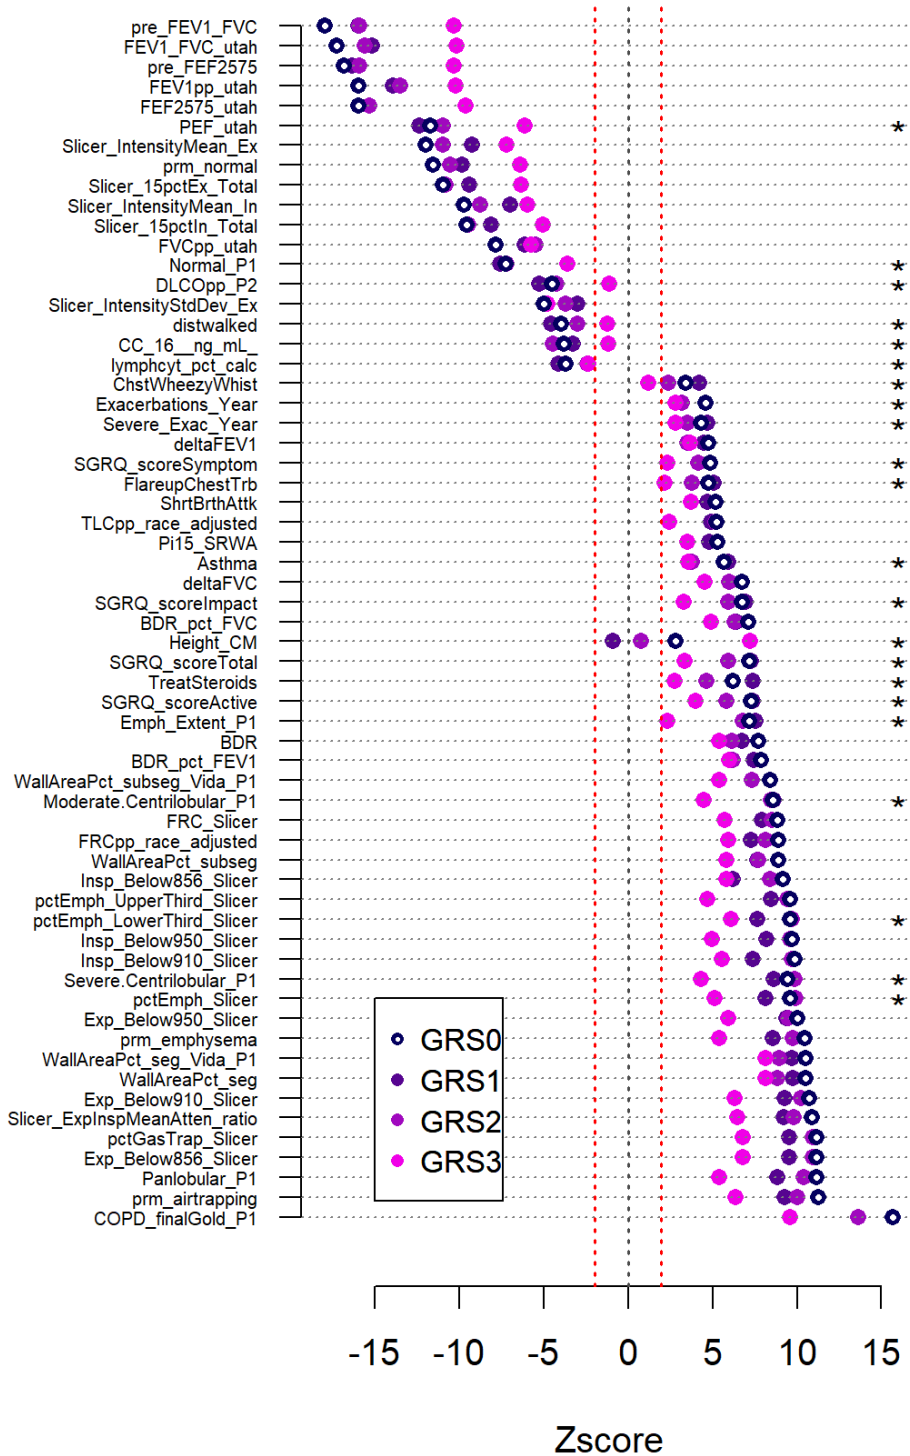

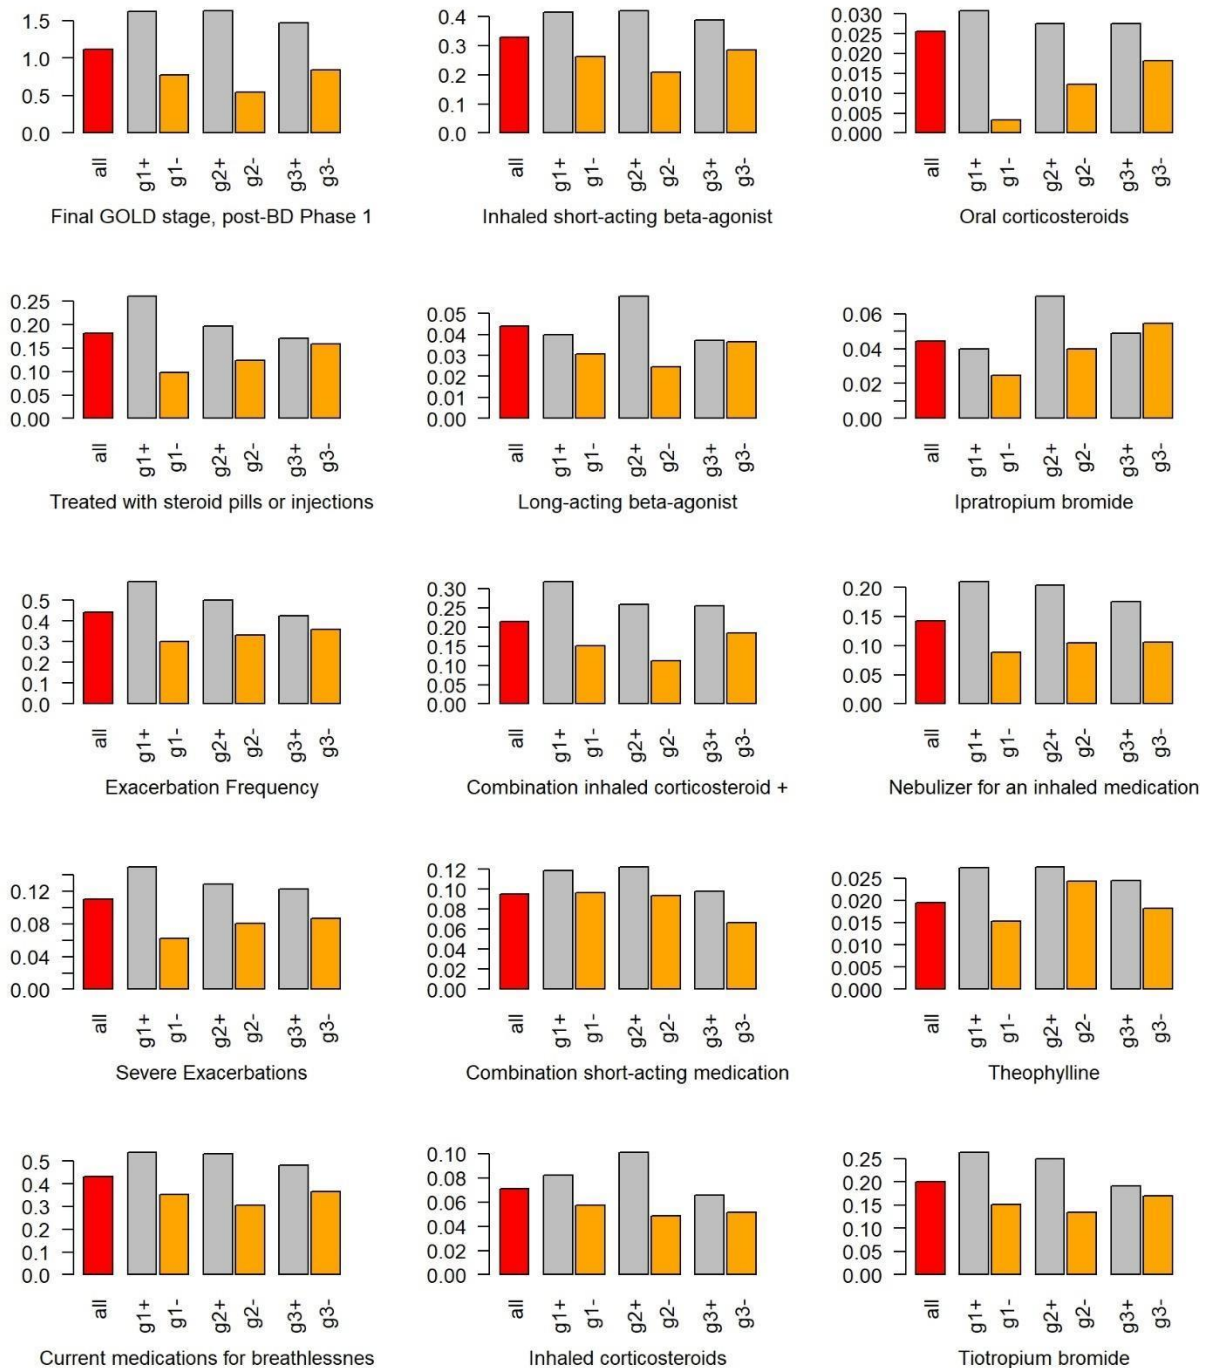

Figure S5. Frequency of treatments in COPDgene conditional on the genetic risk score

We derived the frequency of COPD treatments in the whole COPDgene cohort (red bars) and in sub-samples defined based on the three genetic risk scores (GRS). Frequencies in the top 5% percentile of GRS1 (g1+), GRS2 (g2+), and GRS3 (g3+) are indicated by grey bars, and frequencies in the lowest 5% percentiles of GRS1 (g1-), GRS2 (g2-), and GRS3 (g3-) are indicated by orange bars. Final Gold stage (panel top left) was included for comparison purposes.
