2 Methods

2.1 Participants

Inclusion criteria: native German speaker; right-handed; no diagnosis of schizophrenia, psychosis or autism, or any neurological disease or injury; not currently taking any psychoactive medication within at least the past six weeks and no contraindications for MRI scanning.

Subjects: Out of the participants, three had been previously diagnosed with depression, two had prior eating disorders, one was diagnosed with schizoid personality disorder along with adjustment disorder, and another reported having post-traumatic stress disorder and narcissistic personality disorder. However, only one of the participants was consistently taking antipsychotic medication (fluoxetine, atomoxetine) for attention deficit disorder.

Details of demographic data and symptom scores are shown in Table S2 and have been previously published in (10).

Table S2: Demographic data and clinical scores.

	Female (n = 26)	Male (n = 27)	P-value ^a	W
Age	23.31 (3.54)	23.93 (4.21)	0.7266	331
SPQ: Positive-like Symptoms (/132)	35.96 (23.54)	28.70 (25.20)	0.1846	426
SPQ: Negative-like Symptoms (/100)	37.85 (15.57)	34.33 (20.49)	0.3454	404
SPQ: Disorganized Traits (/64)	23.19 (14.27)	21.22 (13.12)	0.7285	371
AQ: Total Score (/50)	21.65 (6.99)	20.96 (7.65)	0.7017	373

3 Results

3.1 Spectral quality

We applied the paired Wilcoxon signed-rank test for multiple pairwise comparisons of the CRLB and the multiple pairwise paired t-tests for the SNR between basis sets. P-values were adjusted using the Bonferroni multiple-testing correction method. An adjusted p-value of less than 0.05 was considered significant. Results are presented in Table S3 and Table S4.

4 Discussion

4.1 Group differences between the metabolite concentration estimates

Comparisons between the estimates for Glx are summarized in **Figure S2**. Adding PCr to the basis sets leads to a decrease in the Glx concentrations for both the Rowland(9) and the Kozhuharova(5) basis sets as well as in both toolboxes. Estimates were consistently lower for the analysis in spant+ABfit compared to the ones analyzed with Osprey+LCM. Necessary to note is also that the Rowland+PCr and LCModel basis sets are now identical, which can be nicely seen in the boxplots.

4.2 Correlations of each metabolite estimate between the basis sets

As already mentioned in the manuscript, the correlations between metabolite (Glu/tCr, absolute Glu, Glx) and basis set per toolbox revealed that the metabolite concentrations between the basis sets had higher correlations using Ospreys LCM integration than spant+ABfit. For Osprey+LCM, we found strong

correlations between all basis sets ($r > 0.75$). Comparing the Rowland (9) and Kozhuharova (5) basis sets with added PCr to the ones without, the “new” basis sets show higher correlations with the three visually best-fitting basis sets (LCModel Manual (4), Maddock et al. (2), and Reid et al. (3); **Figure 3 B, C, and D**) with Spearman correlation coefficients between 0.95-1 for Osprey+LCM and 0.87-0.97 for spant+ABfit, the three visually best-fitting basis sets (LCModel Manual (4), Maddock et al. (2), and Reid et al. (3); **Figure 3 B, C, and D**) showed the best results with spearman correlation coefficients between 0.93-1 for Osprey+LCM and 0.88-0.94 for spant+ABfit (**Figure S3**). Correlation strength was classified according to Akoglu (11).

4.3 Association between the concentrations and traits

Finally, we also analyzed Spearman's rank correlations for clinical scores with the extracted concentration scores for the two basis sets with added PCr. Overall, the results in Osprey+LCM and ant+ABfit displayed now a more homogenous pattern regarding their correlations. Using the Rowland (9) and Kozhuharova (5) basis set with PCr instead of the ones without this metabolite, the maximum difference between the correlation coefficients of Glx and disorganized traits in Osprey+LCM decreased from 0.18 to 0.04. The same can be seen in spant+ABfit where the maximal difference was changing from 0.42 to 0.16 for this correlation. However, the difference between the toolboxes was still smaller than the difference across the different basis sets and reached a maximum of 0.11, again for the correlation of Glx and disorganized traits. The correlations are shown in **Figure S2**.

Figure S2: Basisets + PCr: Group comparisons for Glx in the ACC and Correlations between the metabolite concentrations and clinical scores

Note: A) Group comparisons between the basis sets (Rowland (12), Rowland + PCr, LCMModel (4), Kozuharova +PCr, Kozuharova (5) for absolute Glx values; Spearman correlations between Glu/tCr (Glu/Cr for Rowland and Kozuharova), absolute Glu, Glx, and the subclinical traits for the basis sets B)

Rowland + PCr and C) (5); the left side always shows the results for spant+ABfit and the right side for Osprey+LCM. The psychotic-like traits are separated into the subscores: positive-like symptoms, negative-like symptoms, and disorganized traits.

Figure S3: Basis sets + PCr and tool box intercorrelations

Note: Intercorrelations between the basis sets (Rowland (12), Rowland+PCr, LCModel (4), Maddock (2), Reid (3), Kozuharova (5) and Kozuharova+PCr) and toolboxes (spant+ABfit; Osprey) for A) Glu/tCr (Glu/Cr for Rowland and Kozuharova), B) Glu, C) Glx
