

Supplementary Methods

Multiple Factor Analysis: reduction of the dimensionality

A multiple factor analysis (MFA) was performed to reduce the dimensionality of the data and to obtain a composite for each class of regional WMH. The MFA works by performing both group-specific and a global principal component analysis (PCA). We were interested in the group-specific PCA. The main goal was to obtain the first principal component (PC1) from each PCA that explained the highest variability in the data.

A component should satisfy the following properties:

1. Each component is a linear combination of the initial variables.
2. Pairs of components are uncorrelated.
3. Components are sorted in decreasing order regarding the variance they explain.

The obtention of the components works as follows:

- (1) Regional WMHV for six brain regions (infratentorial, basal ganglia, frontal, parietal, occipital and temporal) are grouped in three main blocks based on the distance to the ventricles: periventricular, deep or juxtacortical and the spatial distribution. A total of 18 variables are available, 6 per group.
- (2) Group-specific PCA are performed for each WMH subtype. The PC1 of each group-specific PCA is selected and corresponds to the combination of the 6 region-specific WMHV that explains the highest variability in the sample. All PCA-components are defined as linear combinations of all region-specific volumes and are uncorrelated between them. Subsequent principal components explain the rest of variability in the data.
- (3) The first principal components for each subtype are defined in the models as outcomes for regional WMHV: PC1 periventricular WMHV, PC1 deep WMHV and PC1 juxtacortical WMHV.

Principal components description

PC1 periventricular WMHV

The PC1 for periventricular WMHV explained 90% of periventricular WMHV variability in the sample. The most important variables contributing to the component were the frontal periventricular WMH along with the parietal and basal ganglia WMH. The temporal, occipital and infratentorial variables had a weaker contribution to the component.

Supplementary Figure 4. Principal component analysis results for periventricular WMHV. On the left is described the variability explained by each independent component. On the right, the contribution of each variable to the first component.

PC1 deep WMHV

The PC1 for deep WMHV explained 79% of the variability for deep WMHV in the sample. The most important variables contributing to the component were the frontal deep WMH along with the parietal and temporal WMH. The occipital, basal ganglia and infratentorial variables had a weaker contribution to the component.

Supplementary Figure 5. Principal component analysis results for deep WMHV. On the left is described the variability explained by each independent component. On the right, the contribution of each variable to the first component.

PC1 juxtacortical WMHV

The first principal component for juxtacortical WMHV explained 88% of the variability for juxtacortical WMHV in the sample. The most important variables contributing to the component were the frontal juxtacortical WMH along with the parietal and temporal WMH. The occipital, basal ganglia and infratentorial variables had a weaker contribution to the component, same as for the deep WMHV.

Supplementary Figure 6. Principal component analysis results for juxtacortical WMHV. On the left is described the variability explained by each independent component. On the right, the contribution of each variable to the first component.

Supplementary Figure 1. Flowchart of the sample of the study. *Legend: ALFA (Alzheimer's and Families), WMH (White matter hyperintensities). All individuals had available quantification of WMHV, genetic data and predicted 20-years risk of dementia based on cardiovascular risk factors.*

Supplementary Figure 2. Variables included in the predicted 20-years risk of dementia based on cardiovascular risk factors (CAIDE-I). *Legend: the probability of dementia late in life according to the CAIDE-I risk score categories are (i) CAIDE-I [0-5]: 1%; (ii) CAIDE-I [6-7]: 1.9%; (iii) CAIDE-I [8-9]: 4.2%; (iv) CAIDE-I [10-11]: 7.4% and CAIDE-I [12-15]: 16.4% (Kivipelto et al., 2006).*

A) WMH volume across Fazekas-based groups

B) PRS-WMH across Fazekas-based groups

Supplementary Figure 3. Mean value and standard error of global WMHV along the WMH severity continuum based on the Fazekas scale. *Global WMHV were adjusted for TIV and expressed per 100mm³.*

<i>N° of SNPs included in the PRS after the clumping with $p\text{-value} < 5 \cdot 10^{-6}$</i>	25

Supplementary Table 2: Detailed information of the GWAS of reference and the summary statistics for the PRS-WMH computation. *Legend:* GWAS (Genome-wide association study); SNP (single nucleotide polymorphism); N (sample size); PRS (Polygenic risk score). The optimal threshold for the p -value was determined to be $5 \cdot 10^{-6}$ as it included a sufficient number of SNPs to capture genetic variability in the sample and accounted for the highest variance in WMH volumes compared to the rest of scores.

Supplementary Table 5. Enrichment analysis results for the SNPs-related genes of the PRS-WMH before the clumping.

Legend: GeneRatio: ratio of input genes that are annotated in a term ($\text{GeneRatio} = k/n$, where k : overlap of the SNPs-related gene IDs with the specific gene set related to a biological pathway; n : size of the overlap of the SNPs-related gene IDs with all the members of the collection of gene sets); BgRatio: ratio of all genes that are annotated in a term ($\text{BgRatio} = \text{count}/\text{setSize}$, where count : number of genes that belong to a given gene-set; setSize : total number of genes in the collection of gene sets); P-value: probability of seeing at least X number of genes out of the total n SNPs-related gene IDs in the list annotated to a particular GO term, given the proportion of genes in the whole genome that are annotated to that GO term; FDR: p-value after false discovery rate correction; Q-value: proportion of false positives incurred when the test is significant (FDR correction among the significant results); Counts: number of genes annotated to the GO term.

Supplementary Table 6. Enrichment analysis results for the SNPs-related genes of the PRS-WMH after the clumping.

Legend: GeneRatio: ratio of input genes that are annotated in a term ($\text{GeneRatio} = k/n$, where k : overlap of the SNPs-related gene IDs with the specific gene set related to a biological pathway; n : size of the overlap of the SNPs-related gene IDs with all the members of the collection of gene sets); BgRatio: ratio of all genes that are annotated in a term ($\text{BgRatio} = \text{count}/\text{setSize}$, where count : number of genes that belong to a given gene-set; setSize : total number of genes in the collection of gene sets); P-value: probability of seeing at least X number of genes out of the total n SNPs-related gene IDs in the list annotated to a particular GO term, given the proportion of genes in the whole genome that are annotated to that GO term; FDR: p -value after false discovery rate correction; Q-value: proportion of false positives incurred when the test is significant (FDR correction among the significant results); Counts: number of genes annotated to the GO term.
