

Supplementary Note: Comparison of standard and ultra-rapid ddPCR thermal conductance and surface area to volume ratios

Here, we estimate the thermal conductances of the ddPCR 96-well plate well used in standard ddPCR and the stainless-steel capillary used in ultra-rapid ddPCR. Thermal conductance, C , is the rate at which a material of a given thickness conducts heat. It is calculated as $C = K/T$ and measured in Watts/(meter²*Kelvin), i.e., $W/(m^2 \cdot K)$, where K is the thermal conductivity (a heat transfer constant specific to a given material) measured in Watts/(meter*Kelvin) and T is the thickness of the material, measured in meters.

The thermal conductivity of polypropylene, the plastic used in the ddPCR 96-well plates, has been measured to be $0.22 \text{ W/(m} \cdot \text{K)}$ ¹, and the thermal conductivity of stainless-steel 304, the material of our capillaries, is approximately $15 \text{ W/(m} \cdot \text{K)}$ ². Since the thickness of the ddPCR plate wells was not available to us, we measured the thickness of 33 wells of a ddPCR 96-well plate at their thinnest point using a micrometer and obtained an estimate of $0.30 \pm 0.07 \text{ mm}$. The thickness of the stainless-steel capillary is $0.10 \pm 0.04 \text{ mm}$ per the manufacturer. Thus, the thermal conductance of the ddPCR plate well is approximately $7.3 \times 10^2 \text{ W/(m}^2 \cdot \text{K)}$ and the thermal conductance for the stainless-steel capillary is approximately $1.5 \times 10^5 \text{ W/(m}^2 \cdot \text{K)}$, which is an ~ 204-fold difference.

We also estimated the surface area to volume ratio of a standard ddPCR reaction occurring in a ddPCR 96-well plate and an ultra-rapid ddPCR reaction occurring in a stainless steel capillary. We estimated the volume of the slanted portion of an individual well of a ddPCR 96-well plate as a truncated cone using bottom and top diameters of 2.16 mm and 5.60 mm, respectively, and a height of 11.10 mm as estimated from the manufacturer's blueprint, which yielded a volume of 139.84 μL . Using these values, we also calculated the surface area of the slanted portion of the ddPCR plate well to be 136.92 mm^2 . Thus, the surface area to volume ratio of a standard ddPCR well is $0.98 \text{ mm}^2/\mu\text{L}$. For the stainless-steel capillary, we calculated its volume as a cylinder with length 57.15 mm and an inner diameter of 1.067 mm (per the manufacturer), which yielded 51.10 μL . Using these values, we also calculated the outer surface area of the capillary, which is the area contacting the heated water during ultra-rapid ddPCR, to be 191.57 mm^2 . Thus, the surface area to volume ratio of the capillary is $3.75 \text{ mm}^2/\mu\text{L}$, which is 3.8-fold higher than that of the ddPCR plate well.
