

**Supplementary Figure 4. Increased inflammatory immune responses in melioidosis and tuberculosis patients with diabetes.** Functional pathway analysis based on KEGG gene sets following differential gene expression (DGE) analysis between melioidosis patients compared to uninfected healthy donors and tuberculosis (TB) patients compared to uninfected healthy donors. (A) Up-regulated KEGG pathways derived from the DGE analyses among TB and melioidosis patients compared to their respective uninfected healthy control cohorts. (B) Down-regulated KEGG pathways derived from the DGE analyses among TB and melioidosis patients compared to their respective uninfected healthy control cohorts. The gradient colour bar corresponds to the adjusted P-value. The size of each term is indicated by representative counts (number of DEGs). Differentially expressed genes were pre-filtered based on a cut-off of absolute[Log2 fold-change]  $\geq 1$  and adjusted P-value  $<0.05$ . Gene set enrichment analysis based on Hallmark gene sets following differential gene expression (DGE) analysis among tuberculosis patients across four study sites. (C) TB patients with intermediate hyperglycaemia (TB-IH, n=44) compared to TB patients without DM (TB-only, n=46). (D) TB patients with diabetes (TB-DM, n=61) compared to TB patients without DM (TB-only, n=46). Normalised enrichment scores are displayed, in which pathways were deemed significant when adjusted P-value  $<0.05$ .
