

Mixed-effects models

For calculating limits of agreement: $(\text{trial 2} - \text{trial 1 score}) = \text{test sitting} + (1 | \text{PID})$

For calculating the cohort mean difference: $(\text{trial 2} - \text{trial 1 score}) = 1 + (1 | \text{PID})$

Supplementary Figure 1

Diagnostic plots for the models that make up the mixed-effects Bland-Altman plot. **(A-B)**
Diagnostic plots for the limits of agreement model. **(C-D)** Diagnostic plots for the mean difference model.

Supplementary Figure 2

Plots of PASAT scores against clinical features, volumetric MRI, and smartphone dominant hand tapping.

Supplementary Figure 3

Plots of written SDMT scores against clinical features, volumetric MRI, and smartphone dominant hand tapping.

Supplementary Figure 4

Plots of app SDMT scores against clinical features, volumetric MRI, and smartphone dominant hand tapping.

Supplementary Figure 5

Explanation diagram for how elastic net works.

Supplementary Figure 6

A

B

C

Age and SDMT distributions (app and written) between the cohorts in elastic net regression. The training cohort has 86 individuals and the validation set has 38 individuals. Wilcoxon rank-sum test determined that age and SDMT scores were not significantly different (ns) between these groups.

Supplementary Figure 7

A

B

C

D

Coefficient path and mean RMSE plots for written and app SDMT elastic net regressions. **(A-B)** Plots for written SDMT. **(C-D)** Plots for app SDMT.

Supplementary Figure 8

Coefficient path and mean RMSE plots for app SDMT elastic net regressions, with and without tapping score as covariate. **(A-B)** Plots for app SDMT with tapping. **(C-D)** Plots for app SDMT without tapping.

Mixed-effects model for calculating ICC with sitting number

$$\text{app SDMT score} = \text{test sitting} + (1 | \text{PID})$$

Supplementary Figure 9

Diagnostic plots for the mixed-effects model that calculate ICC based on scores across number of sittings. **(A-B)** Diagnostic plots for model that includes all longitudinal data. **(C-D)** Diagnostic plots for model that includes only post-learning data.

Supplementary Figure 10

Longitudinal app SDMT scores plotted against days from first test sitting of sitting number.

Mixed-effects model for calculating ICC days difference

app SDMT score = days since first sitting + (1 | PID)

Supplementary Figure 11

Diagnostic plots for the mixed-effects model that calculate ICC based on scores across different days. **(A-B)** Diagnostic plots for model that includes all longitudinal data. **(C-D)** Diagnostic plots for model that includes only post-learning data (determined using the model in suppl. 9). ICC with all data: 0.88. ICC post-learning: 0.91.
