Supplementary methods .....	1
Short-chain fatty acid measurements .....	1
Inflammatory and permeability marker measurements .....	2
Statistical analyses.....	3
Supplementary figures .....	3
Figure S1. Correlations for variables of interest in full data and subsets. ....	3
Figure S2. Scatterplots for significantly correlated clinical variables and SCFAs or inflammatory markers... ..	5
Figure S3. Correlations of inverse Simpson and Shannon diversity for SCFAs and inflammatory markers. ....	6
Figure S4. NMDS ordination plots for beta diversity, control/PD status, and the stool markers and SCFAs associated with the most notable beta diversity differences.....	7
Figure S5. Butyric acid, stool NGAL, and zonulin in different enterotypes among PD patients and control subjects.....	8
Figure S6. Scatter plots of differentially abundant genera for SCFAs.....	9
Figure S7. Scatter plots of differentially abundant genera for stool inflammatory markers.....	10
Supplementary tables.....	11
Table S1. Marker and SCFA concentrations by PD/control status and sex .....	11
Table S2. Linear regression for alpha diversity, inflammatory and permeability markers/SCFAs, and PD/control status.....	12
Table S3. Beta diversity, inflammatory and permeability markers/SCFAs and PD status.....	13
Table S4. Differences in inflammatory and permeability marker/SCFA levels between enterotypes.....	14
Table S5. Differentially abundant taxa for variables of interest. ....	15

## **Supplementary methods**

### **Short-chain fatty acid measurements**

Detection and quantification of SCFAs in the stool samples were performed at the Norwegian University of Life Sciences using a Trace 1310 gas chromatograph (Thermo Fisher Scientific, USA) equipped with an autosampler, a split/splitless injector, a flame ionization detector, and a Stabilwax DA column (30 m, 0.25 mm ID, 0.25 µm film; Thermo Fisher Scientific, USA). Samples were suspended in MilliQ water (1:1 w/v) and subsequently homogenized by vortexing using glass beads (size: 2.5-3.5 mm) in the solution. The samples were then diluted with 0.2% formic acid and 500 µM of an internal standard (2-methylvaleric acid; 1:1 w/v) before a 5 min centrifugation step at 13 000 rpm. The internal standard was included to control equal sampling volume and was used for normalization of the samples. 300 µl of the supernatant was applied to spin columns (0.2 µm filter; VWR, USA) and centrifuged at 10 000 rpm for 5 min. The eluate was transferred to 300 µl GC vials (VWR) and analyzed in the GC-FID instrument. A standard solution was made with final concentrations of 0.1% formic acid and 1000 µM of each of the acids (acetic acid, propionic acid, butyric

acid, isobutyric acid, valeric acid, and 2-methylvaleric acid). All acids were purchased from Sigma-Aldrich, Germany. Samples were injected into the GC system in volumes of 0.2 µl. Split mode was set to 2.5:200, and injector and detector temperatures were set to 250 and 275 °C respectively. Helium was used as a carrier gas. Temperature intervals comprised a 2-min step at 90 °C followed by a 6-min increase to 150 °C and a 2-min increase to 245 °C followed by a hold at this temperature for 4.9 min. The software Chromeleon 7.2 (Thermo Fisher Scientific) was used for instrument control, quantification, and data analysis.

### Inflammatory and permeability marker measurements

To prepare stool for the Zonulin Stool ELISA (ALPCO catalog # 30-ZONHU-E01) kit, the dilution/extraction buffer was prepared according to the manufacturer's instructions and added to thawed raw stool samples at a ratio of 1 mg stool to 50 mL buffer. The assay was then performed according to the manufacturer's protocol. Reference absorbance values (absorbance at 620 nm) were subtracted from absorbance values at 450 nm, and zonulin concentrations were interpolated from a standard curve using a quadratic regression according to manufacturer's recommendations and multiplied by the dilution factor (50) to obtain actual concentrations in the stool (ng/mg).

For measurements of stool calprotectin, neutrophil gelatinase-associated lipocalin (NGAL), and cytokines, frozen stool samples were suspended in homogenization buffer (125 mM Tris, 15 mM MgCl<sub>2</sub>, 2.5 mM EDTA pH 7.2, 1% Triton X-100, 1 tablet protease inhibitors [1697498, Roche] per 10 mL buffer) and homogenized in a TissueLyser-II (QIAGEN, 20 Hz) with a 5 mm metal bead (QIAGEN). Debris were pelleted, and supernatants were collected. The total protein concentration in each supernatant was measured by BCA assay (Pierce) according to the manufacturer's protocol, and samples were diluted to 6 mg/mL in homogenization buffer.

For the LEGEND MAX™ Human MRP8/14 (Calprotectin) ELISA Kit (Biolegend catalog # 439707), 6 mg/mL stool samples were diluted 1:20 in assay buffer A, and 50 µL (15 µg protein) were loaded into wells. The assay was performed according to the manufacturer's protocol. Reference absorbance values (absorbance at 570 nm) were subtracted from absorbance values at 450 nm, and calprotectin concentrations were interpolated from a standard curve using a quadratic regression according to manufacturer's recommendations and multiplied by the dilution factor (20) to obtain actual concentrations in the stool lysate (ng/mL).

Stool NGAL levels were measured using the LEGEND MAX™ Human NGAL (Lipocalin-2) ELISA Kit (Biolegend catalog # 443407). 6 mg/mL stool samples were diluted 1:50 in assay buffer B, and 50 µL (6 µg protein) were loaded into wells. The assay was performed according to the manufacturer's protocol and analyzed in the same way as calprotectin.

The cytokines interferon gamma (IFNy), interleukin (IL)-1β, IL-2, IL-4, IL-6, CXCL8, IL-10, IL-12p70, IL-13, and tumor necrosis factor (TNF) were measured in stool and plasma by multiplexed immunoassay using the V-PLEX Proinflammatory Panel 1 Human Kit (Meso Scale Discovery, MSD, Rockville, MD, catalog # K15049D). 6 mg/mL stool lysates were diluted 1:1 in diluent 2, and 50 µL (150 µg) of each sample were loaded. Fifty microliters of undiluted plasma were loaded for each test. The multiplexed immunoassay was performed according to the manufacturer's protocol using the MSD QuickPlex instrument, and the results were evaluated on the MSD software platform. Resulting values were multiplied by the dilution factor to obtain actual concentrations in the stool lysates and plasma (pg/mL).

Lipopolysaccharide binding protein (LBP) concentrations (µg/mL) were measured in plasma using the Human LBP Kit (MSD catalog # K151IYC) on the MSD platform according to the manufacturer's protocol.

All samples were run in duplicate in each assay, and roughly equal numbers of control and PD subject samples were included on each plate. In the multiplexed immunoassays, stool and plasma samples from each subject were run on the same plate. No systematic differences were observed in values obtained from different runs.

## Statistical analyses

We performed all statistical analyses in R,<sup>32</sup> and managed microbiota data with the phyloseq package.<sup>33</sup> The full analysis workflow is available as a supplementary file (Supplementary R Markdown). For statistical comparisons between SCFAs/markers, clinical variables, enterotypes, and alpha diversity, we used the Kruskal-Wallis test, Wilcoxon rank sum test, or Pearson correlations depending on the types of variables. When multiple comparison corrections were included, we used the Benjamini & Hochberg false discovery rate, correcting SCFAs, stool markers, and plasma markers separately. Principal Component Analysis (PCA) was used to merge intercorrelated inflammatory markers.

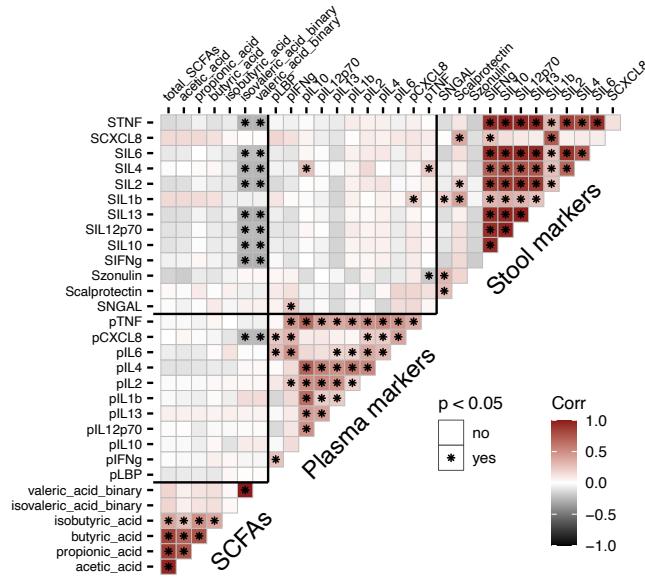

In all microbiome-related comparisons, we tested the full data (patients and control subjects together), and PD-only and control-only subsets. Additionally, we ran confounder-corrected comparisons specific to each test. For alpha and beta diversity comparisons, we used OTU-level data subsampled to the lowest number of reads in a sample (7165). Alpha diversity comparisons included two measures: Shannon and inverse Simpson (both indices include richness and evenness); after preliminary screening with correlations, we explored the most interesting cases with linear regression - corrected for PD/control and sex - with the SCFA or marker variables log-transformed to address heteroskedasticity. Beta diversity was evaluated with PERMANOVAs on Bray-Curtis distance matrices, run with the adonis (univariable) and adonis2 (multivariable) tests from the vegan package<sup>34</sup>, and visualized with Non-Metric Multidimensional scaling (NMDS). The variables in confounder-corrected adonis2 models were sex, Rome III 9-15 sum score, and BMI. For differential abundance testing, we used DESeq2<sup>35</sup> on trimmed data (genera and families with > 5 reads in > 50% of the samples), and ran four models: full data, PD-only, control-only, and full data corrected for PD/control status, Rome III 9-15 sum score, and sex.

## Supplementary figures

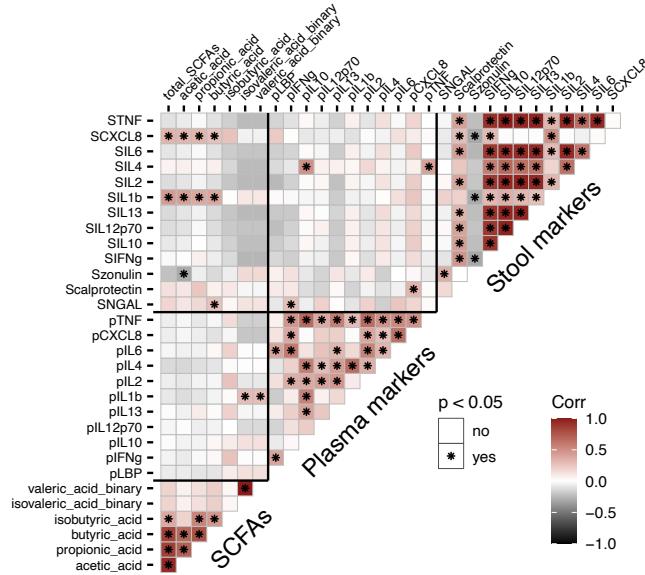

**Figure S1. Correlations for variables of interest in full data and subsets.**

\* : p < 0.05.

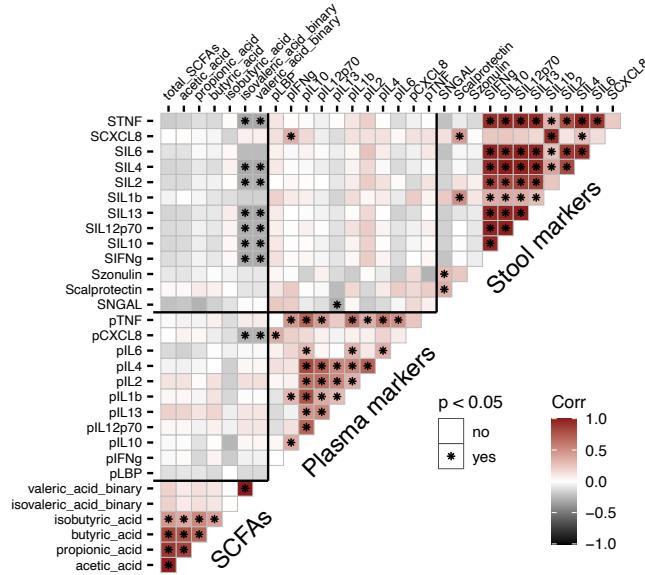

### A. Full data

```

## 1.1 Data import

Import inflammatory marker data, mark as NA the values that are over the measurement range for calprotectin and NGAL, and trim subjects that only have values for LBP:

```
inf_df <- read.csv("Inputs/cytokine_data.csv", row.names = 1)

# Save the variable names for further use:
inf_vars <- colnames(inf_df)
inf_vars_s <- grep("^S", inf_vars, value = TRUE) # Stool variables
inf_vars_p <- grep("^p", inf_vars, value = TRUE) # Plasma variables

# Change the "TOO HIGH" values in stool NGAL to NA
inf_df$SNGAL <- as.character(inf_df$SNGAL)
inf_df$SNGAL[inf_df$SNGAL == "TOO HIGH"] <- NA
inf_df$SNGAL <- as.numeric(inf_df$SNGAL)

# Change the "TOO HIGH" values in stool calprotectin to NA
inf_df$Scalprotectin <- as.character(inf_df$Scalprotectin)
inf_df$Scalprotectin[inf_df$Scalprotectin == "TOO HIGH"] <- NA
inf_df$Scalprotectin <- as.numeric(inf_df$Scalprotectin)

# Samples with more than one missing value?
print(inf_df[names(which(rowSums(is.na(inf_df)) > 1)), ])
```

	pLBP	SNGAL	Scalprotectin	Szonulin	SIFNg	SIL10	SIL12p70	SIL13	SIL1b			
## C0052	4.653704	NA		NA	NA	NA	NA	NA	NA			
## C0124	4.283837	NA		NA	NA	NA	NA	NA	NA			
##	SIL2	SIL4	SIL6	SCXCL8	STNF	pIFNg	pIL10	pIL12p70	pIL13	pIL1b	pIL2	pIL4
## C0052	NA	NA	NA	NA	NA	NA	NA	NA	NA	NA	NA	NA
## C0124	NA	NA	NA	NA	NA	NA	NA	NA	NA	NA	NA	NA
##	pIL6	pCXCL8	pTNF									
## C0052	NA	NA	NA									

```

## C0124    NA      NA    NA
# Two samples have NA for everything except pLBP. Drop these two:
inf_df <- inf_df[-(which(rowSums(is.na(inf_df)) > 1)), ]

```

Import clinical metadata and SCFA measurements, trim to subjects fit to use based on the follow-up analyses (Aho et al. 2019):

```

clin_df <- read.csv("Inputs/pdcy_meta_v4.csv", row.names = 1)

# Subset to follow-up timepoint samples deemed "OK to use"
clin_df <- subset(clin_df, Timepoint == "followup" & OK_to_use == "yes")

# Remove timepoint identifier from row names
rownames(clin_df) <- sub("N", "", rownames(clin_df))

# Make sure factor variables are in correct form
for(i in colnames(clin_df)){
  if(identical(names(table(clin_df[, i])), c("0", "1")) | is.factor(clin_df[, i])){
    clin_df[, i] <- factor(clin_df[, i])}

# Two additional variables need to be fixed manually:
clin_df$tobacco_when_last <- factor(clin_df$tobacco_when_last)
clin_df$meds_rasagiline_mg <- as.numeric(as.character(clin_df$meds_rasagiline_mg))

# Remove some redundant variables
clin_df$OK_to_use <- NULL
clin_df$Timepoint <- NULL

# Remove variables with a lot of missing values
clin_df <- clin_df[, -which(colSums(is.na(clin_df)) > 100)] 

# Remove variables with a lot of zeros
clin_df <- clin_df[, -which(colSums(clin_df == 0, na.rm = TRUE) > 120)]
```

Import enterotype variable and add to clinical data:

```

pd_et <- read.csv("Inputs/enterotyping_results.txt", row.names = 1)

# Trim to follow-up only
pd_et <- pd_et[grep("N", rownames(pd_et)), ]
rownames(pd_et) <- sub("N", "", rownames(pd_et))

# Add to main metadata df
clin_df$Enterotype <- pd_et[rownames(clin_df), "ET"]
```

Trim subjects with missing values for any of the big three SCFAs:

```

# Make a list of the SCFA variables
scfa_vars <- grep("_acid", colnames(clin_df), value = TRUE)
# Reorder for convenience
scfa_vars <- scfa_vars[c(1, 2, 4, 3, 5:6)]

# Exclude subjects with missing values for any of the big 3 SCFAs
clin_df <- subset(clin_df, !rowSums(is.na(clin_df[, scfa_vars[1:3]])) > 0)
```

Add a “total SCFAs” sum variable:

```

clin_df$total_SCFAs <- rowSums(clin_df[, scfa_vars], na.rm = TRUE)
scfa_vars <- c("total_SCFAs", scfa_vars)

```

Combine the immune marker data and the rest of the metadata:

```

# Match the immune marker data to the trimmed clinical data
inf_df <- inf_df[rownames(clin_df), ]

# Combine the two dfs
pdcy_meta <- cbind(clin_df, inf_df)

```

## 1.2 Outlier check

Plot values of the variables of interest in all samples to see how they are distributed.

### 1.2.0.1 SCFAs

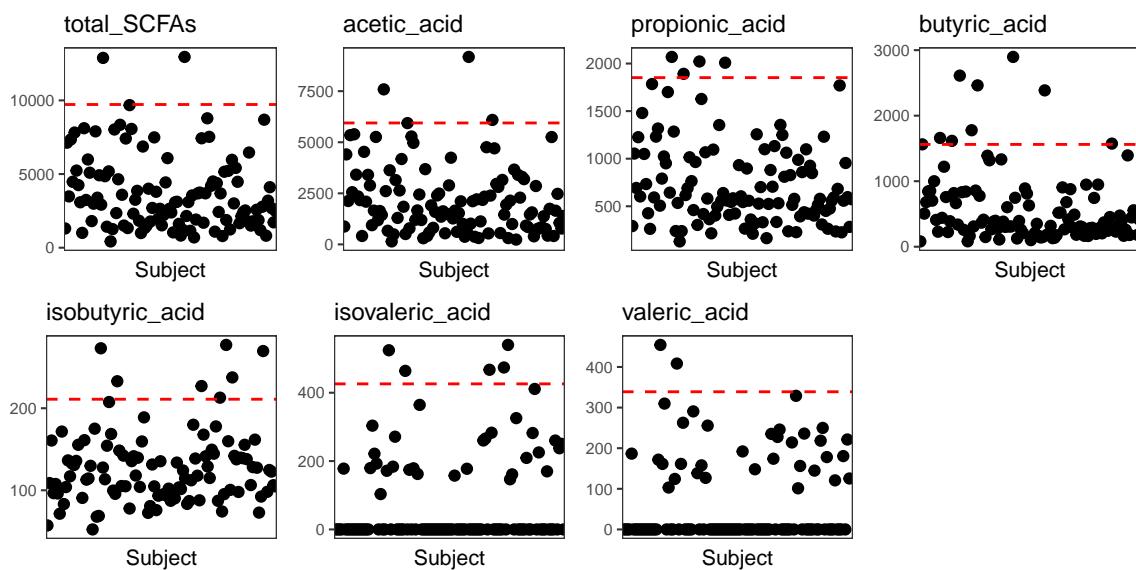

Plot all SCFA measurement values (dashed line is the 3rd quartile + 1.5\*IQR):

```

# Plotting function
ol_plot <- function(df, var){
  ggplot(df, aes_string(x = "Subject", y = var)) +
    geom_point() +
    theme_bw(base_size = 8) +
    ylab(NULL) +
    ggtitle(var) +
    geom_hline(yintercept = (quantile(df[,var], 0.75, na.rm = TRUE) +
                               1.5*IQR(df[,var], na.rm = TRUE)),
               linetype = 2, color = "red") +
    theme(panel.grid = element_blank(),
          axis.text.x = element_blank(),
          axis.ticks.x = element_blank(),
          plot.title = element_text(size = 9))
}

scfa_ol <- lapply(scfa_vars, function(x) ol_plot(pdcy_meta, x))
do.call("grid.arrange", c(scfa_ol, ncol = 4))

```

The SCFA data seemed quite evenly distributed. Since most subjects' value for valeric and isovaleric acid was zero, convert these two into binary variables (0 vs > 0):

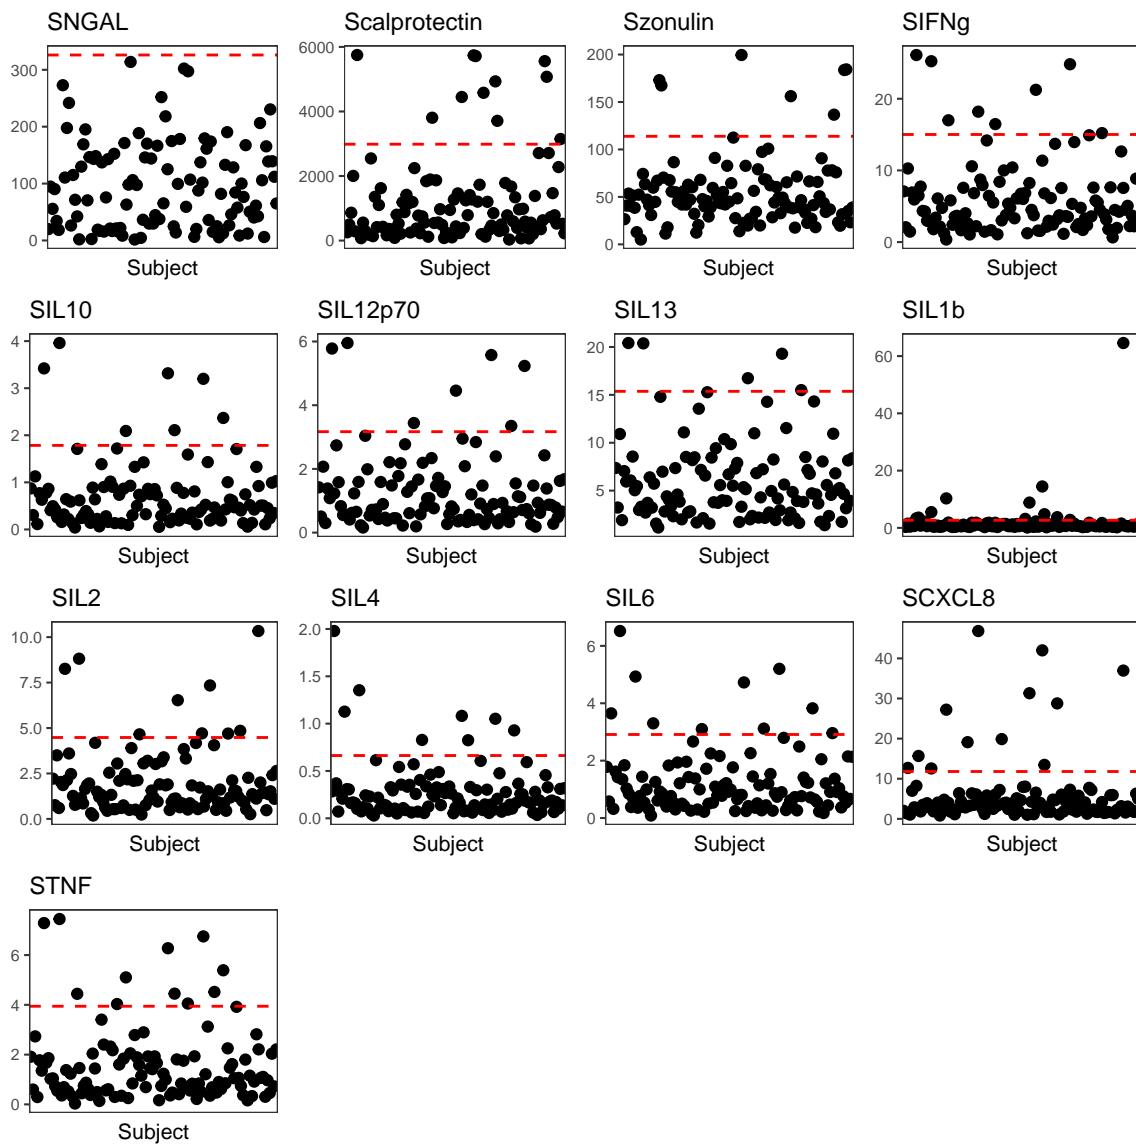

```
# Make new binary variables for the two SCFAs
pdcy_meta$isovaleric_acid_binary <- as.numeric(pdcy_meta$isovaleric_acid > 0)
pdcy_meta$valeric_acid_binary <- as.numeric(pdcy_meta$valeric_acid > 0)

# Replace the numeric variables in the list of SCFA vars with the binary ones
scfa_vars[grep("valeric", scfa_vars)] <- paste(scfa_vars[grep("valeric", scfa_vars)],
                                                "binary", sep = "_")
```

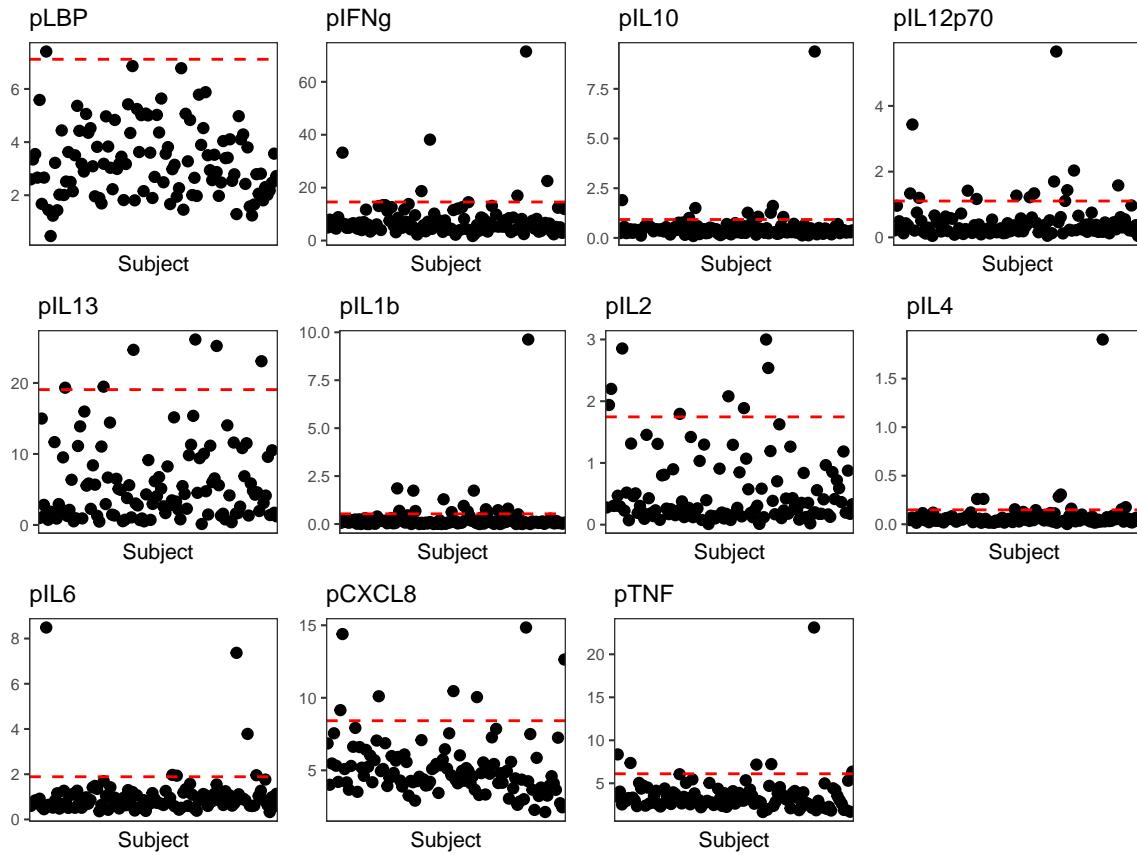

### 1.2.0.2 Inflammatory markers

Plot all inflammatory marker values:

```
inf_ol <- lapply(c(inf_vars_s, inf_vars_p), function(x) ol_plot(pdcy_meta, x))
do.call("grid.arrange", c(inf_ol[1:13], ncol = 4))
```

```
do.call("grid.arrange", c(inf_ol[14:24], ncol = 4))
```

There was a single, extreme outlier point in SIL1b, pIL10, pIL1b, pIL4 and pTNF. The subjects of these points were:

```
sapply(c("SIL1b", "pIL10", "pIL1b", "pIL4", "pTNF"), function(x)
  as.vector(pdcy_meta[which(pdcy_meta[, x] == max(pdcy_meta[, x])), "Subject"]))
```

```
##   SIL1b   pIL10   pIL1b   pIL4   pTNF
## "P0099" "P0071" "P0071" "P0071" "P0071"
```

For plasma measurements, the outlier was the same subject. To make sure this subject would not cause problems, exclude them from the data. Replace the one outlier SIL1b value with NA.

```
pdcy_meta[pdcy_meta$Subject == "P0099", "SIL1b"] <- NA
pdcy_meta <- subset(pdcy_meta, Subject != "P0071")
```

### 1.3 Subjects and demographics

After the exclusions, the number of samples remaining for the analyses was as follows:

```
kable(table(pdcy_meta$Group), col.names = c("Group", "n"), booktabs = TRUE)
```

Group	n
C	56
P	55

```
# Export the final metadata for possible future use
write.csv(pdcy_meta, "Outputs/pdcy_meta_from_R.csv")
```

### 1.3.0.1 Table 1

Make tables of basic demographics and measures for the samples:

#### Categorical confounders

```
# List all binary variables
clin_table_cat_vars <- names(which(lengths(sapply(pdcy_meta, levels)) == 2))
# Exclude PD vs C
clin_table_cat_vars <- grep("Group", clin_table_cat_vars, invert = TRUE, value = TRUE)

# Summarize
clin_table_cat <- sapply(clin_table_cat_vars,
  function(x){
    out <- c(paste(levels(pdcy_meta[, x])[2]),
      prop.table(
        table(pdcy_meta[,c("Group", x)]), 1)[1,2]*100,
      prop.table(
        table(pdcy_meta[,c("Group", x)]), 1)[2,2]*100,
      fisher.test(
        table(pdcy_meta[,c("Group", x)]))$p.value)
    names(out) <- c("var", "C", "P", "pVal")
    return(out)})}

# Reorganize
clin_table_cat <- as.data.frame(t(clin_table_cat))
clin_table_cat$var <- capitalize(
  gsub("_", " ", paste0(rownames(clin_table_cat), " (% ",
    sub(1, "yes", clin_table_cat$var), ")")))
clin_table_cat[, 2:4] <- sapply(clin_table_cat[, 2:4], function(x)
  as.numeric(as.character(x)))

# Trim to significant variables + sex
clin_table_cat_sig <- rbind(clin_table_cat["sex",],
  subset(clin_table_cat, pVal < 0.05))

# Show
kable_styling(kable(clin_table_cat_sig, digits = 4,
  booktabs = TRUE, row.names = FALSE,
  linesep = ""), font_size = 8)
```

### 1.3.0.2 Table S1

Descriptive values and *p*-values for PD/control and the variables of interest (SCFAs + inflammatory markers):

```
# List variables of interest (with isovaleric and valeric acid as numeric)
basic_pdc_vars <- c(scfa_vars[1:5], "isovaleric_acid", "valeric_acid",
                     inf_vars_s, inf_vars_p)

# Summarize
table_basic_pdc <- sapply(basic_pdc_vars, function(x) meanSdP(pdcy_meta, x))

# Function for fixing variable names
varLabelFix <- function(x){
  capitalize(
    gsub("_", " ", sub("^(p([A-Z]{1}))", "Plasma \\\\"1", sub("^S", "Stool ", x))))
}

# Reorganize and make nicer row labels
table_basic_pdc <- as.data.frame(t(table_basic_pdc))
table_basic_pdc <- data.frame(var = varLabelFix(rownames(table_basic_pdc)),
                                table_basic_pdc)

# Show
kable_styling(kable(table_basic_pdc, booktabs = TRUE, row.names = FALSE,
                    linesep = "\n"), font_size = 8)
```

  ncol = 1)
grid.arrange(marker_scfa_cor_plots)

```

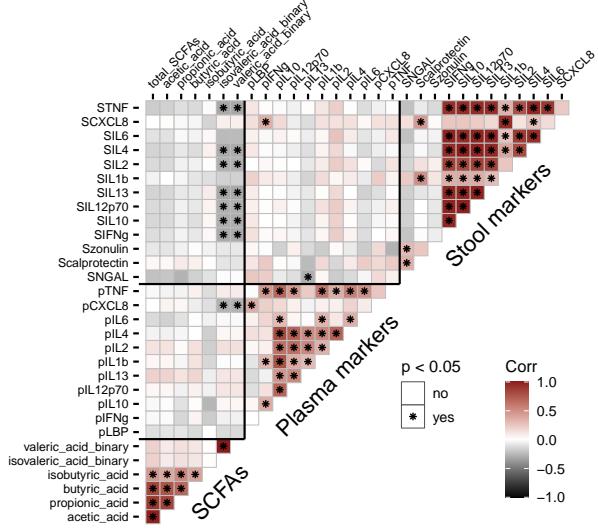

### A. Full data

### B. Control only

### C. PD only

```
ggsave(marker_scfa_cor_plots,
       filename = "Outputs/figS1_scfa_marker_cors.pdf",
       width = 4.5, height = 12, units = "in")
```

## 2.2 PCA with inflammatory markers

Since many of the markers were intercorrelated, use Principal Component Analysis to condense those variables (goal: decrease the number of variables in comparisons and avoid collinearity issues).

### 2.2.1 Stool

For stool, leave out NGAL, calprotectin, zonulin, IL1b and CXCL8 (which were less strongly intercorrelated with other variables) and include the rest of the variables.

```
infs_PCA_vars <- inf_vars_s[!(inf_vars_s %in% c("SNGAL", "Scalprotectin", "Szonulin",
                                                "SIL1b", "SCXCL8"))]

# Scale the values
infs_scaled <- scale(pdcy_meta[, infs_PCA_vars])
infs_scaled <- as.data.frame(infs_scaled[1:nrow(infs_scaled), ])

# Calculate PCA
infs_PCA <- prcomp(as.formula(paste("~", paste(infs_PCA_vars, collapse = " + "))),
                     data = infs_scaled, na.action = na.omit)
```

The proportion of variance explained by the PCA axes as a plot:

```
fviz_screeplot(infs_PCA, ncp = 15) +
  theme_bw(base_size = 9) +
  ylab("Percentage of unexplained variances") +
  theme(panel.grid.major.x = element_blank())
```

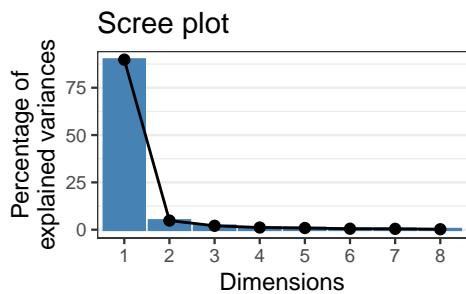

Table of metrics for all principal components:

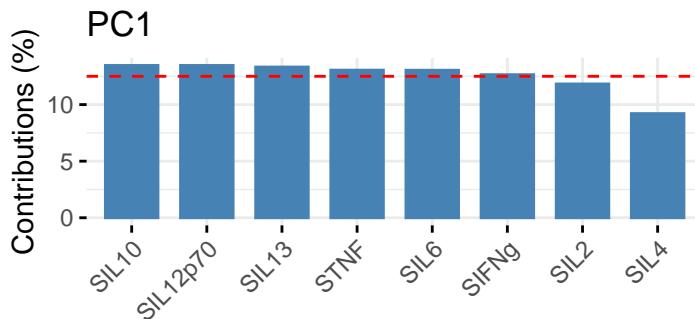

```
kable(summary(infs_PCA)$importance, digits = 3, booktabs = TRUE)
```

	PC1	PC2	PC3	PC4	PC5	PC6	PC7	PC8
Standard deviation	2.681	0.622	0.406	0.304	0.268	0.203	0.191	0.140
Proportion of Variance	0.898	0.048	0.021	0.012	0.009	0.005	0.005	0.002
Cumulative Proportion	0.898	0.947	0.967	0.979	0.988	0.993	0.998	1.000

The first PC captured almost 90% of all variance. It's probably enough to just keep the first axis for further analyses.

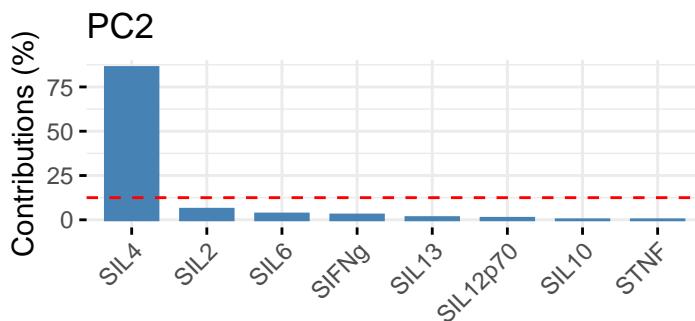

Plots of the variables contributing to the first three principal components:

```
fviz_contrib(infs_PCA, choice = "var", axes = 1) + ggttitle("PC1")
```

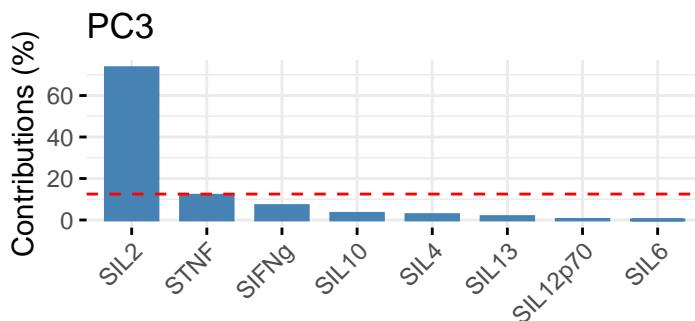

PC1 had significant contributions from most ILs, TNF and IFNg, with IL2 and IL4 falling beneath the reference line.

```
fviz_contrib(infs_PCA, choice = "var", axes = 2) + ggttitle("PC2")
```

PC2 corresponded to IL4.

```
fviz_contrib(infs_PCA, choice = "var", axes = 3) + ggttitle("PC3")
```

PC3 corresponded to IL2.

Plots of the first three axes, with the PD and control subjects marked:

```
library("ggfortify")

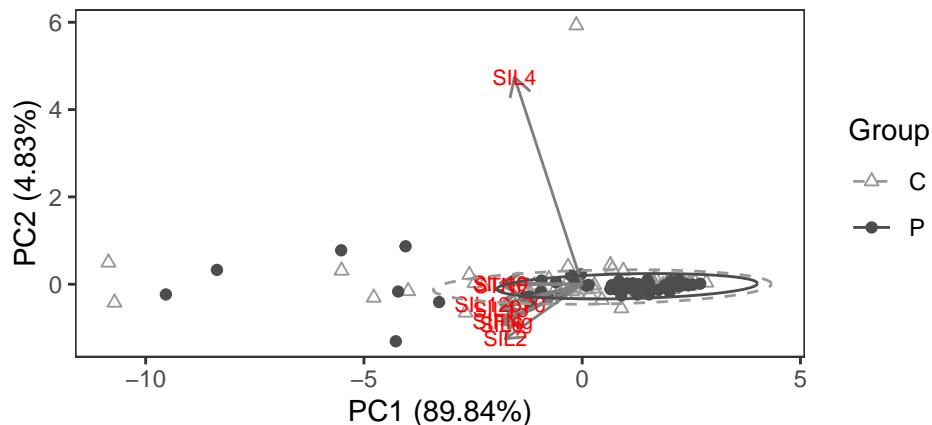

pcaPlotPD <- function(pcdat, df, x, y){
  autoplot(pcdat, data = df, x = x, y = y, colour = "Group", shape = "Group",
            loadings = TRUE, loadings.colour = "gray50", loadings.label = TRUE,
            loadings.label.size = 2.75, scale = 0) +
  theme_bw() +
  coord_fixed() +
  stat_ellipse(aes(group = Group, color = Group, lty = Group), level = 0.9) +
  scale_color_manual(values = c("gray60", "gray30"), name = "Group") +
```

```

    scale_shape_manual(values = c(2, 19), name = "Group") +
    scale_linetype_manual(values = c(2, 1), name = "Group") +
    theme(panel.grid = element_blank())
}

pcaPlotPD(infs_PCA, pdcy_meta[rownames(infs_PCA$x), ], 1, 2)

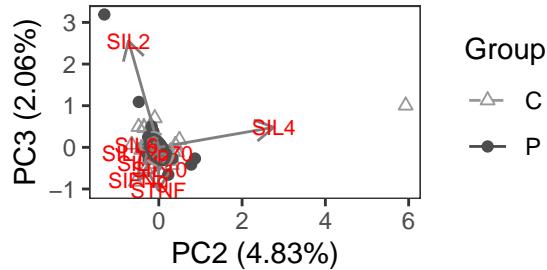

```

```
pcaPlotPD(infs_PCA, pdcy_meta[rownames(infs_PCA$x), ], 1, 3)
```

```
pcaPlotPD(infs_PCA, pdcy_meta[rownames(infs_PCA$x), ], 2, 3)
```

Export PC1 and add to the metadata as “StoolPC” - a summary variable representing IFNg, IL10, IL12p70, IL13, IL6 and TNF. Keep IL4 and IL2 as individual variables.

```

infs_PC1 <- data.frame(infs_PCA$x[, 1])

# Export
write.csv(infs_PC1, "Outputs/infs_pca.csv")

# Add to full data
pdcy_meta$StoolPC <- infs_PC1$rownames(pdcy_meta), ]

```

```
# New list of variables of interest for stool (stool markers + PC1)
infs_vars <- c("SNGAL", "Scalprotectin", "Sztonulin", "SCXCL8", "SIL1b",
              "SIL4", "SIL2", "StoolPC")
```

## 2.2.2 Plasma

For plasma marker PCA, leave out LBP, IFNg, IL6 and CXCL8, which were not as strongly intercorrelated as the rest of the variables, and run the analysis with the remaining variables.

```
infp_PCA_vars <- infp_vars_p[!(infp_vars_p %in% c("pLBP", "pIFNg", "pCXCL8", "pIL6"))]

# Scale the values
infp_scaled <- scale(pdcy_meta[, infp_PCA_vars])
infp_scaled <- as.data.frame(infp_scaled[1:nrow(infp_scaled), ])

# Calculate PCA
infp_PCA <- prcomp(as.formula(paste("~", paste(infp_PCA_vars, collapse = " + "))),
                     data = infp_scaled, na.action = na.omit)
```

The proportion of variance explained by the resulting PCA axes as a plot:

```
fviz_screenplot(infp_PCA, ncp = 15) +
  theme_bw(base_size = 9) +
  ylab("Percentage of unexplained variances") +
  theme(panel.grid.major.x = element_blank())
```

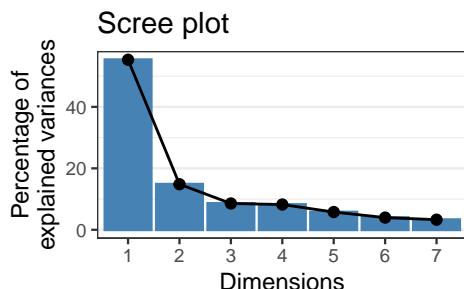

Table of metrics for all principal components:

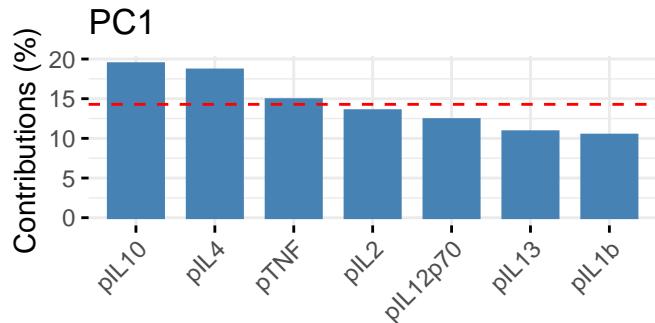

```
kable(summary(infp_PCA)$importance[1:3, ], digits = 3, booktabs = TRUE)
```

	PC1	PC2	PC3	PC4	PC5	PC6	PC7
Standard deviation	1.968	1.019	0.774	0.759	0.636	0.527	0.480
Proportion of Variance	0.553	0.148	0.086	0.082	0.058	0.040	0.033
Cumulative Proportion	0.553	0.702	0.787	0.870	0.927	0.967	1.000

The situation was not as clear as for the stool variables, but PC1 did explain 55% of all variance. One could consider keeping either just PC1, or the first two PCs.

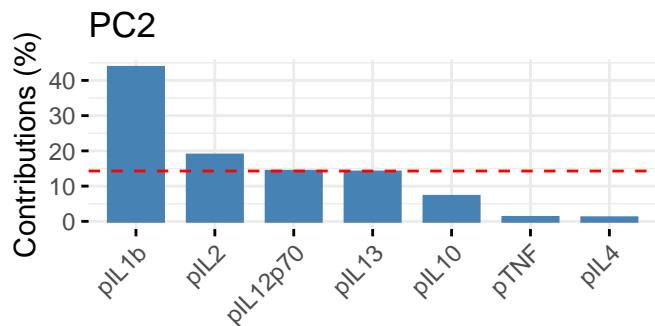

Plots of the variables contributing to the first four principal components:

```
fviz_contrib(infp_PCA, choice = "var", axes = 1) + ggttitle("PC1")
```

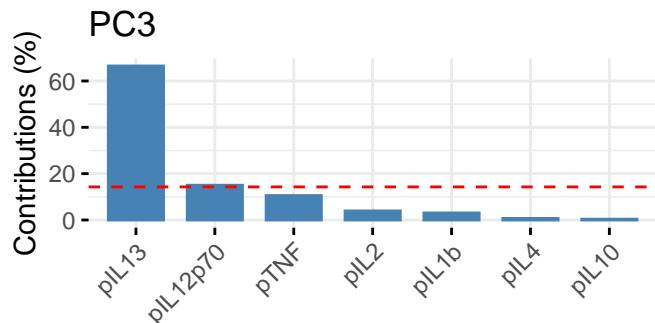

PC1 had contributions mostly from IL10, IL4 and TNF.

```
fviz_contrib(infp_PCA, choice = "var", axes = 2) + ggttitle("PC2")
```

PC2 was mainly IL1b, with minor contributions from IL2, IL12p70 and IL13.

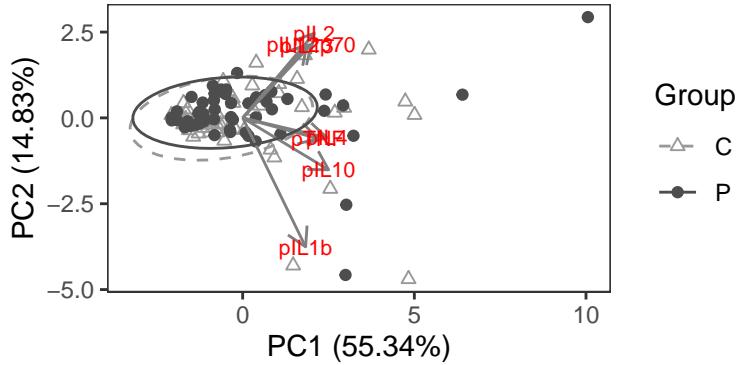

```
fviz_contrib(infp_PCA, choice = "var", axes = 3) + ggttitle("PC3")
```

PC3 was mostly IL13 and a minor contribution from IL12p70.

Plot of PC1 and PC2, with the PD and control subjects marked:

```
pcaPlotPD(infp_PCA, pdcy_meta[rownames(infp_PCA$x), ], 1, 2)
```

Export the first two axes for downstream use:

```
infp_PCs <- data.frame(infp_PCA$x[, 1:2])

# Export
write.csv(infp_PCs, "Outputs/infp_pca.csv")

# Add to data
infp_PCs <- infp_PCs[rownames(pdcy_meta), ]
pdcy_meta$pPC1 <- infp_PCs$PC1
pdcy_meta$pPC2 <- infp_PCs$PC2

# New list of variables of interest for plasma
infp_vars <- c("pLBP", "pIFNg", "pCXCL8", "pIL6", "pPC1", "pPC2")

# Final list of marker/SCFA variables of interest
inf_scfa_vars <- c(scfa_vars, infs_vars, infp_vars)

# Full list of all marker/SCFA variables (including redundant ones)
inf_scfa_all_vars <- unique(c(inf_scfa_vars, inf_vars_s, inf_vars_p,
                               "valeric_acid", "isovaleric_acid"))
```

## 2.3 Correlations between clinical variables

To test for correlations between variables, run a correlation matrix for the inflammatory markers, SCFAs, and potential confounding variables that are either numeric or binary factors. Run tests for full data and control-only and PD-only subsets, with the PD-only comparisons including additional variables that are only relevant to PD patients.

```
# Numeric variables
cor_vars <- names(which(sapply(pdcy_meta, is.numeric)))

# Binary variables
cor_vars_b <- names(which(sapply(pdcy_meta, function(x) length(levels(x))) == 2))
# Make binary numeric variables out of the factor ones
cor_vars_b_num <- sapply(pdcy_meta[, cor_vars_b], as.numeric)

# Put together data matrix
cor_data <- cbind(as.matrix(pdcy_meta[, cor_vars]), cor_vars_b_num)
cor_data <- cor_data[, order(colnames(cor_data))]

# Full list of all confounding variables
conf_vars <- colnames(cor_data)
```

```

# Exclude some non-relevant or too uncommon variables +
# the PD vs control, SCFA and marker variables
conf_vars <- conf_vars[!(conf_vars %in% c("Group", "LED", "DBS",
                                         "history_gyn_prolapse",
                                         "history_gyn_prolapse_repair",
                                         "functional_constipation_criteria_fulfilled",

### 2.3.1.3 Linear regression corrected for age and/or time from disease onset

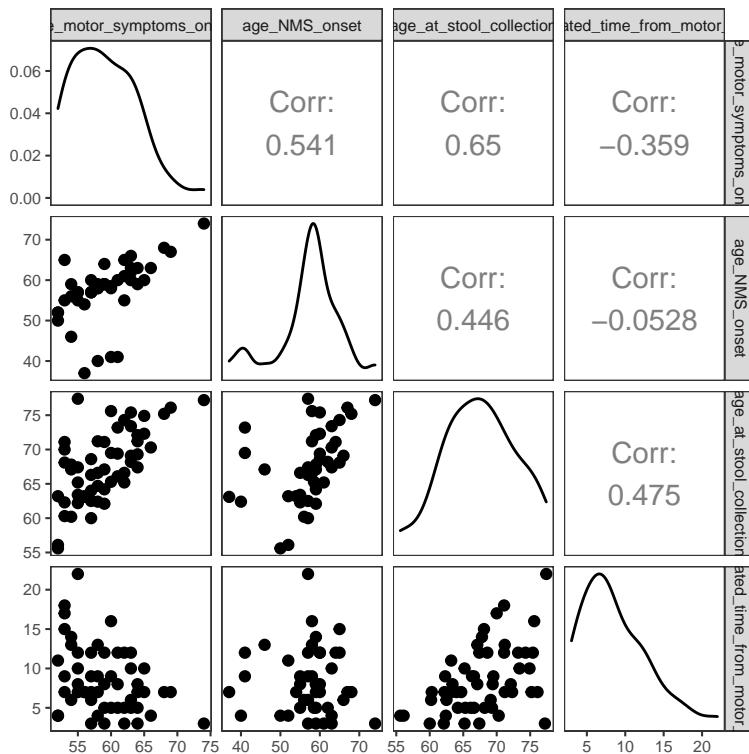

The PD-related correlations are interesting, but should be corrected for some confounding factors, mainly age and disease duration. Prior to corrections, check the potential confounding variables for collinearity.

Butyric acid ~ age motor symptoms onset:

```

ggpairs(subset(
  pdcy_meta, Group == "P")[,c("age_motor_symptoms_onset",
                                "age_NMS_onset",
                                "age_at_stool_collection",
                                "calculated_time_from_motor_onset")]) +
  theme_bw(base_size = 8) +
  theme(panel.grid = element_blank())

```

All three variables are somewhat correlated; use the less collinear one (calculated time from motor onset) for correction.

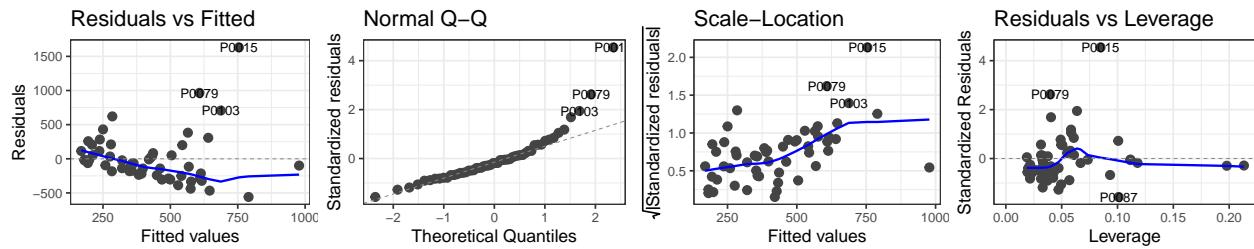

Model for butyric acid ~ time from motor onset: run and plot residuals.

```

buty_motors_regr <- lm(butyric_acid ~ age_motor_symptoms_onset +
                         calculated_time_from_motor_onset,
                         data = subset(pdcy_meta, Group == "P"))

```

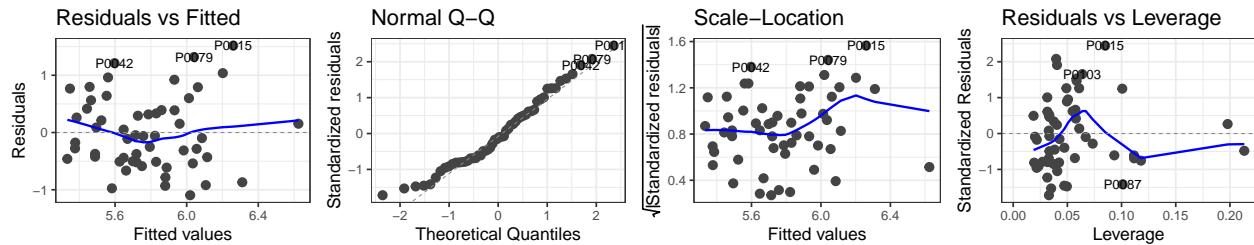

```
autoplot(buty_motors_regr, label.size = 2, nrow = 1) +
  theme_bw(base_size = 8)
```

The diagnostic plots don't look very good - log-transform butyric acid and plot again:

```
buty_motors_regr <- lm(log(butyric_acid) ~ age_motor_symptoms_onset +
  calculated_time_from_motor_onset,
  data = subset(pdcy_meta, Group == "P"))
```

```
autoplot(buty_motors_regr, label.size = 2, nrow = 1) +
  theme_bw(base_size = 8)
```

This looks better; use the log-transformed variable. Show model summary:

```
summary(buty_motors_regr)
```

```
##
## Call:
## lm(formula = log(butyric_acid) ~ age_motor_symptoms_onset + calculated_time_from_motor_onset,
##     data = subset(pdcy_meta, Group == "P"))
##
## Residuals:
##      Min        1Q        Median         3Q        Max 
## -1.09495 -0.49156 -0.07992  0.39073  1.51757 
##
## Coefficients:
##             Estimate Std. Error t value Pr(>|t|)    
## (Intercept) 2.89638   1.24023   2.335   0.0235 *  
## age_motor_symptoms_onset 0.05098   0.01958   2.604   0.0121 *  
## calculated_time_from_motor_onset -0.01471   0.02253  -0.653   0.5166  
## ---    
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 0.6478 on 51 degrees of freedom
##   (1 observation deleted due to missingness)
## Multiple R-squared:  0.1595, Adjusted R-squared:  0.1265 
## F-statistic: 4.838 on 2 and 51 DF,  p-value: 0.01192
```

Age motor symptoms onset is still significant after correction.

What about age NMS onset (still using log-transformed butyric acid)?

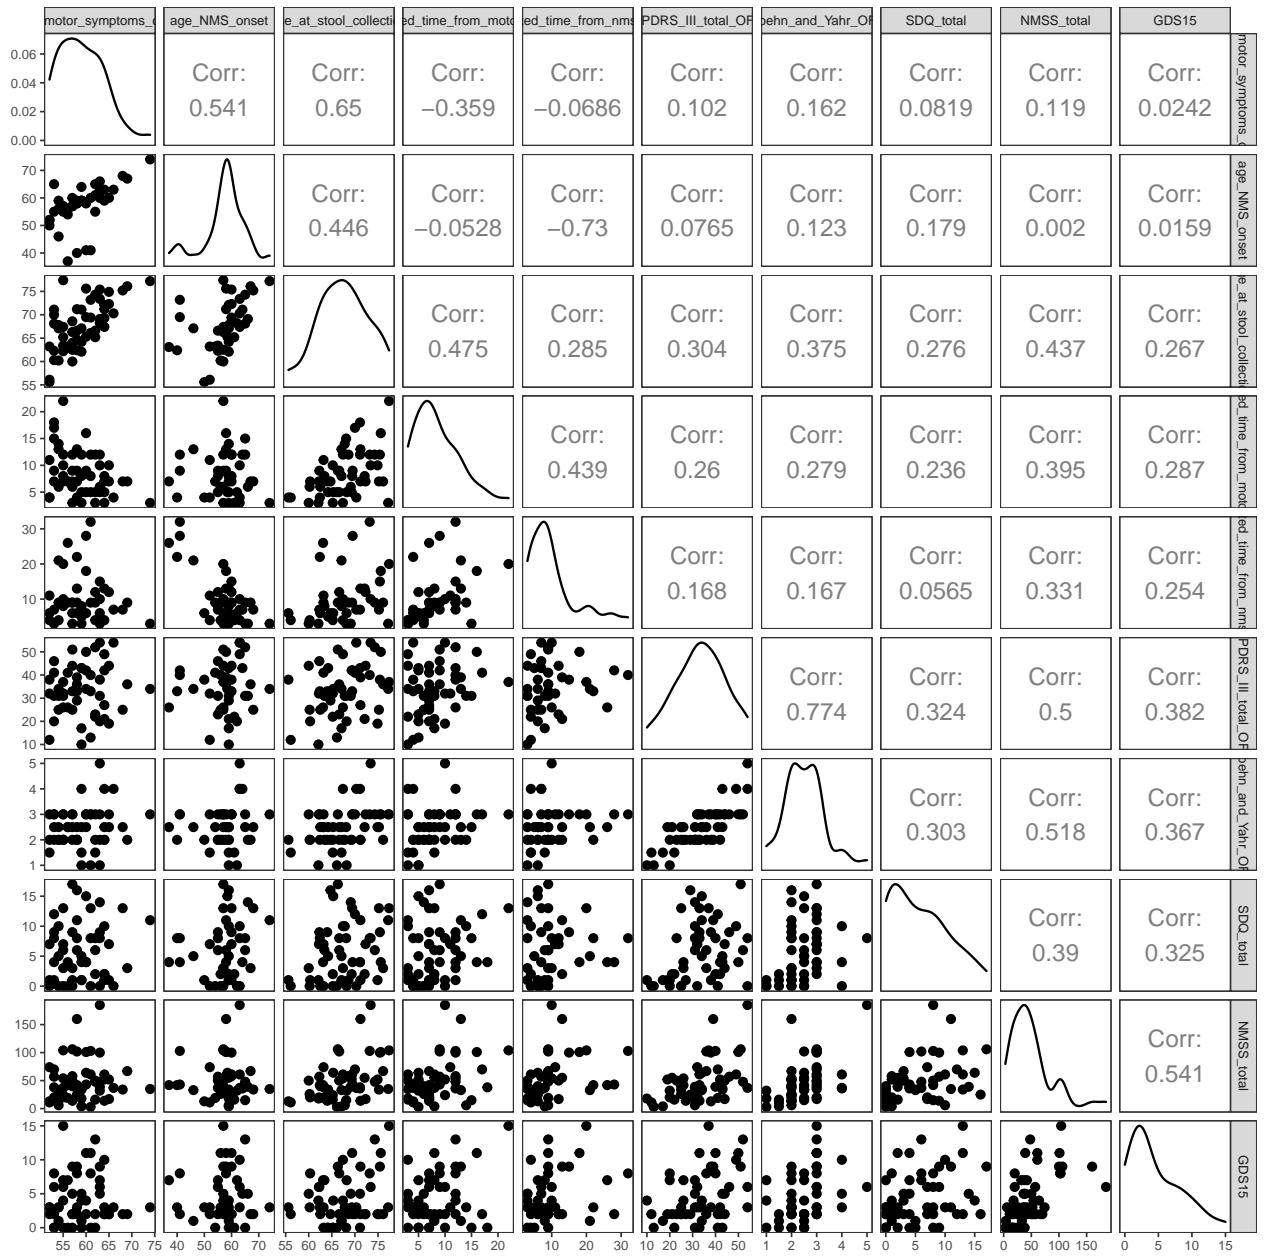

```
summary(lm(log(butyric_acid) ~ age_NMS_onset +
            calculated_time_from_motor_onset,
            data = subset(pdcy_meta, Group == "P")))

##
## Call:
## lm(formula = log(butyric_acid) ~ age_NMS_onset + calculated_time_from_motor_onset,
##      data = subset(pdcy_meta, Group == "P"))
##
## Residuals:
##     Min      1Q  Median      3Q      Max 
## -1.0909 -0.5257 -0.1332  0.3247  1.7834 
##
## Coefficients:
##                               Estimate Std. Error t value Pr(>|t|)    
## (Intercept)             4.88412   0.84704   5.766  9.3e-07 ***
## age_NMS_onset          0.01996   0.01399   1.427   0.161    
## calculated_time_from_motor_onset -0.03539   0.02517  -1.406   0.167    
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 0.687 on 41 degrees of freedom
## (11 observations deleted due to missingness)
## Multiple R-squared:  0.09366,    Adjusted R-squared:  0.04945 
## F-statistic: 2.119 on 2 and 41 DF,  p-value: 0.1332
```

Age NMS onset is not significant in this model.

Stool zonulin and PD-related variables + potential confounders: check for collinearity:

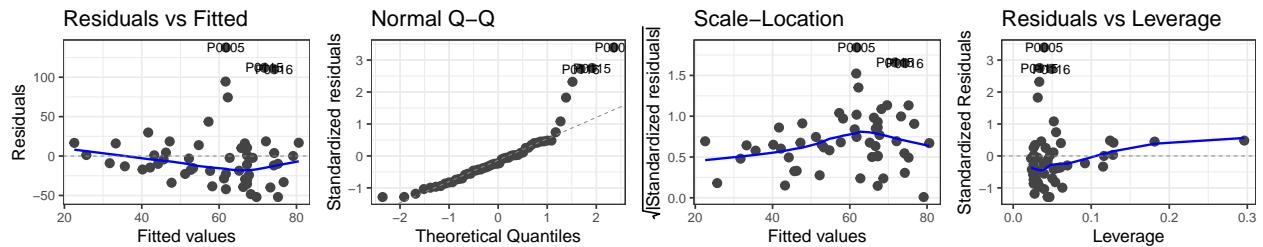

```
ggpairs(subset(
  pdcy_meta, Group == "P")[,c("age_motor_symptoms_onset",
                                "age_NMS_onset",
                                "age_at_stool_collection",
                                "calculated_time_from_motor_onset",
                                "calculated_time_from_nms_onset",
                                "UPDRS_III_total_OFF",
                                "Hoehn_and_Yahr_OFF",
                                "SDQ_total",
                                "NMSS_total",
                                "GDS15")]) +
  theme_bw(base_size = 8) +
  theme(panel.grid = element_blank())
```

The variables of interest are slightly correlated with the age variables, but not very highly.

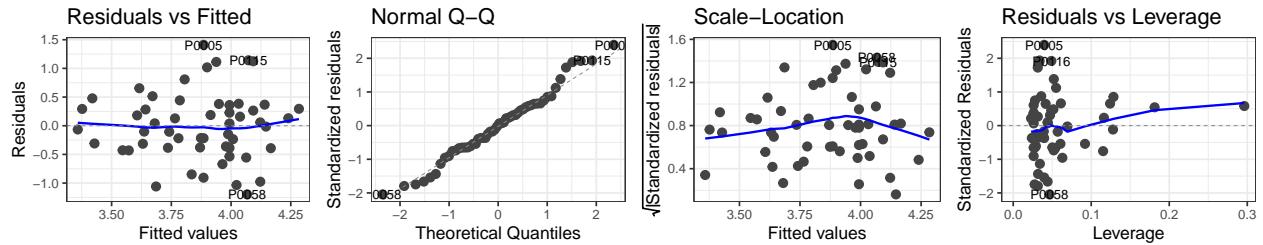

Check residual plots for one example model:

```
autoplot(lm(Szonulin ~ GDS15 +
  calculated_time_from_motor_onset,
  data = subset(pdcy_meta, Group == "P")),
  label.size = 2, nrow = 1) +
  theme_bw(base_size = 8)
```

Similar issues to above; try with log transformation of zonulin:

```
autoplplot(lm(log(Szonulin) ~ GDS15 +
               calculated_time_from_motor_onset,
               data = subset(pdmcy_meta, Group == "P")),
               label.size = 2, nrow = 1) +
  theme_bw(base_size = 8)
```

Though not perfect, this is better; use log-transformed zonulin in all models.

Run regression for all variables of interest with log-transformed zonulin, corrected for calculated time from motor onset:

```
szonulin_motors_regr <- as.data.frame(matrix(ncol = 4, nrow = 0))
colnames(szonulin_motors_regr) <- c("Model", "pValModel",
                                      "pValVar", "pValConf")

for(i in c("UPDRS_III_total_OFF", "Hoehn_and_Yahr_OFF",
          "SDQ_total", "NMSS_total", "GDS15")){
  m <- as.formula(paste("log(Szonulin) ~", i,
                        "+calculated_time_from_motor_onset"))
  res <- summary(lm(m, subset(pdmcy_meta, Group == "P")))
  szonulin_motors_regr <- rbind(szonulin_motors_regr,
                                   data.frame(Model = deparse(m),
                                              pValModel =
                                                unname(pf(res$fstatistic[1],
                                                          res$fstatistic[2],
                                                          res$fstatistic[3],
                                                          lower.tail=FALSE)),
                                              pValVar1 = res$coefficients[2, 4],
                                              pValVar2 = res$coefficients[3, 4]))
}

# Show results
kable_styling(kable(szonulin_motors_regr, digits = 4,
                   booktabs = TRUE, linesep = "",
                   row.names = FALSE), font_size = 8)
```

Model	pValModel	pValVar1	pValVar2
log(Szonulin) ~ UPDRS_III_total_OFF + calculated_time_from_motor_onset	0.0166	0.0045	0.6006
log(Szonulin) ~ Hoehn_and_Yahr_OFF + calculated_time_from_motor_onset	0.0068	0.0017	0.5023
log(Szonulin) ~ SDQ_total + calculated_time_from_motor_onset	0.1517	0.0534	0.6846
log(Szonulin) ~ NMSS_total + calculated_time_from_motor_onset	0.0465	0.0137	0.3459
log(Szonulin) ~ GDS15 + calculated_time_from_motor_onset	0.0309	0.0087	0.4725

All five variables remain significant after correction (and calculated time from motor onset is not significant).

Same, but corrected for age from non-motor symptom onset instead:

```

szonulin_nms_regr <- as.data.frame(matrix(ncol = 4, nrow = 0))
colnames(szonulin_nms_regr) <- c("Model", "pValModel",
                                  "pValVar", "pValConf")

for(i in c("UPDRS_III_total_OFF", "Hoehn_and_Yahr_OFF",
          "SDQ_total", "NMSS_total", "GDS15")){
  m <- as.formula(paste("log(Szonulin) ~", i,
                        "+calculated_time_from_nms_onset"))
  res <- summary(lm(m, subset(pdcy_meta, Group == "P")))
  szonulin_nms_regr <- rbind(szonulin_nms_regr,
                               data.frame(Model = deparse(m),
                                          pValModel =
                                            unname(pf(res$fstatistic[1],
                                                      res$fstatistic[2],
                                                      res$fstatistic[3],
                                                      lower.tail=FALSE)),
                                          pValVar1 = res$coefficients[2, 4],
                                          pValVar2 = res$coefficients[3, 4]))
}

# Show results
kable_styling(kable(szonulin_nms_regr, digits = 4,
                    booktabs = TRUE, linesep = "",
                    row.names = FALSE), font_size = 8)

```

Model	pValModel	pValVar1	pValVar2
log(Szonulin) ~ UPDRS_III_total_OFF + calculated_time_from_nms_onset	0.0133	0.0079	0.3955
log(Szonulin) ~ Hoehn_and_Yahr_OFF + calculated_time_from_nms_onset	0.0159	0.0096	0.3902
log(Szonulin) ~ SDQ_total + calculated_time_from_nms_onset	0.1762	0.1473	0.2710
log(Szonulin) ~ NMSS_total + calculated_time_from_nms_onset	0.0429	0.0270	0.6807
log(Szonulin) ~ GDS15 + calculated_time_from_nms_onset	0.0821	0.0575	0.4954

### 3 Comparisons with microbiota data

Import microbiota data and combine with the metadata:

```

# Import
pd_otus <- as.matrix(read.csv("Inputs/pdfu_16s_OTU_counts.csv", row.names = 1))
pd_tax <- as.matrix(read.csv("Inputs/pdfu_16s_taxonomy.csv", row.names = 1))

# Trim the OTU table to follow-up only
pd_otus <- pd_otus[grep("N", rownames(pd_otus)), ]

```

```

# Remove timepoint identifier from row names
rownames(pd_otus) <- sub("N", "", rownames(pd_otus))

# Match to the samples that are in the metadata
pd_otus <- pd_otus[rownames(pdcy_meta), ]

# Combine data into a phyloseq object
pdcy_phy <- phyloseq(otu_table(t(pd_otus), taxa_are_rows = TRUE),
                      tax_table(pd_tax),
                      sample_data(pdcy_meta))

# Trim out OTUs that have no reads with this subset of samples
pdcy_phy <- subset_taxa(pdcy_phy, taxa_sums(pdcy_phy) > 0)

```

Make summarized objects on different taxonomic levels:

```

# Function for merging phyloseq data to different taxonomic levels:
collapseTaxLevel <- function(phylo_obj, level){

  collapseOtutable <- function(phylo_obj, level){
    tax <- as.data.frame(as(tax_table(phylo_obj), "matrix"))
    otu <- as.data.frame(as(otu_table(phylo_obj), "matrix"))
    otu[, level] <- tax[, level]
    otu_collapsed <- melt(otu, id = (level))
    otu_collapsed <- acast(otu_collapsed,
                           as.formula(paste0(level, "~variable")), sum)
    otu_collapsed <- otu_collapsed[order(rownames(otu_collapsed)), ]
    return(otu_collapsed)
  }

  levelNum <- grep(level, colnames(tax_table(phylo_obj)))

  tax <- as(tax_table(phylo_obj), "matrix")
  tax <- apply(tax, 2, function(x) gsub(".*_unclassified", "unclassified", x))
  phylo_obj <- phyloseq(otu_table(phylo_obj),
                        sample_data(phylo_obj),
                        tax_table(tax))

  otu_collapsed <- collapseOtutable(phylo_obj, level)

  tax <- as(tax_table(phylo_obj), "matrix")
  tax_collapsed <- unique(tax[, 1:levelNum])

  tax_collapsed <- tax_collapsed[-grep("unclassified", tax_collapsed[, levelNum]),]
  tax_collapsed <- rbind(tax_collapsed, rep("unclassified", (levelNum)))

  rownames(tax_collapsed) <- tax_collapsed[, level]
  tax_collapsed <- tax_collapsed[order(rownames(tax_collapsed)), ]

  new_phylo_obj <- phyloseq(otu_table(otu_collapsed, taxa_are_rows = TRUE),
                            tax_table(tax_collapsed),
                            sample_data(phylo_obj))
  return(new_phylo_obj)
}

```

```

# Make genus and family level summarized phyloseq objects:
pdcy_phy_gen <- collapseTaxLevel(pdcy_phy, "Genus")
pdcy_phy_fam <- collapseTaxLevel(pdcy_phy, "Family")

# Subsets of data for downstream comparisons:

# PD-only
pdcy_phy_P <- subset_samples(pdcy_phy, Group == "P")
pdcy_phy_P_gen <- collapseTaxLevel(pdcy_phy_P, "Genus")
pdcy_phy_P_fam <- collapseTaxLevel(pdcy_phy_P, "Family")

# Control-only
pdcy_phy_C <- subset_samples(pdcy_phy, Group == "C")
pdcy_phy_C_gen <- collapseTaxLevel(pdcy_phy_C, "Genus")
pdcy_phy_C_fam <- collapseTaxLevel(pdcy_phy_C, "Family")

```

### 3.1 Alpha diversity

Look for associations between the markers/SCFAs and measures of alpha diversity (within-sample diversity) for two different indices: Shannon and inverse Simpson (both measuring richness and evenness).

#### 3.1.1 Full data (PD + C together)

Calculate alpha diversity index values for full data (subsampled to an even number of reads per sample), and plot the values to check for outliers (dashed line: 3rd quartile + 1.5\*IQR).

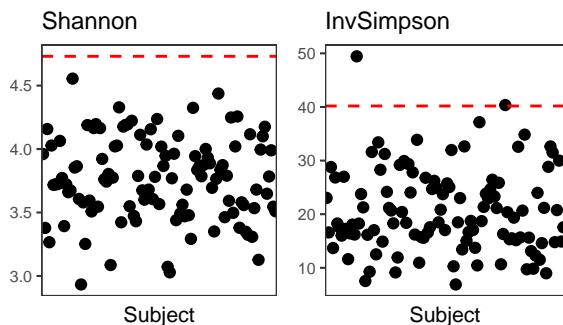

```

# Rarefy data for alpha diversity calculations
pdcy_phy_r <- rarefy_even_depth(pdcy_phy, rngseed = 2441662)

# Calculate alpha diversity values and add to metadata
pdcy_meta <- cbind(pdcy_meta,
                     estimate_richness(pdcy_phy_r, measures = c("Shannon", "InvSimpson")))

# Check what the values look like (to screen for potential outliers etc)
adiv_check <- lapply(c("Shannon", "InvSimpson"), function(x) ol_plot(pdcy_meta, x))
do.call("grid.arrange", c(adiv_check, nrow = 1))

```

One subject had a clearly higher inverse Simpson value than everyone else; replace this subjects' alpha diversity estimates with NAs to exclude them from the comparisons.

```

pdcy_meta[pdcy_meta$InvSimpson == max(pdcy_meta$InvSimpson),
          c("Shannon", "InvSimpson")] <- NA

```

Calculate correlations for alpha diversity vs markers/SCFAs and show results significant for at least one

diversity measure:

```
# Function for calculating correlations
divCors <- function(df, varlist){
  res <- t(sapply(varlist, function(x) c(
    unname(unlist(cor.test(y = df[,x], x = df$Shannon)[c("estimate", "p.value")])), 
    unname(unlist(cor.test(y = df[,x], x = df$InvSimpson)[c("estimate", "p.value")])))))
  colnames(res) <- c("ShanCor", "ShanP", "InvSCor", "InvSP")
  res <- data.frame(Var = varlist, res)
  return(res)
}

# Calculate correlations
adiv_cors_full <- divCors(pdcy_meta, inf_scfa_vars)

# Significant results
kable_styling(kable(subset(adiv_cors_full, rowSums(adiv_cors_full[, c(3, 5)] < 0.05) > 0),
  booktabs = TRUE, linesep = "", digits = 4, row.names = FALSE), font_size = 8)
```

Var	ShanCor	ShanP	InvSCor	InvSP
total_SCFAs	-0.2091	0.0283	-0.1722	0.0720
propionic_acid	-0.2363	0.0129	-0.1694	0.0768
butyric_acid	-0.1950	0.0412	-0.1907	0.0459
SNGAL	-0.3643	0.0001	-0.2787	0.0040
Scalprotectin	-0.2780	0.0034	-0.2325	0.0150
Szonulin	-0.2935	0.0019	-0.2279	0.0167
SIL1b	-0.1890	0.0490	-0.1898	0.0481

### 3.1.2 Control only / PD only

Calculate similar correlations separately for control only and PD only subsets and show significant results:

```
# C-only correlations
adiv_cors_C <- data.frame(divCors(subset(pdcy_meta, Group == "C"), inf_scfa_vars),
  Set = "C_only")

# PD-only correlations
adiv_cors_PD <- data.frame(divCors(subset(pdcy_meta, Group == "P"), inf_scfa_vars),
  Set = "P_only")

# Combine
adiv_cors_sep <- rbind(adiv_cors_C, adiv_cors_PD)

# Order by variable
adiv_cors_sep <- adiv_cors_sep[order(adiv_cors_sep$Var), ]

# Variables with significant hits for either subset
adiv_cors_sep_sigs <- as.character(unique(
  adiv_cors_sep[which(rowSums(adiv_cors_sep[, c(3, 5)] < 0.05) > 0), "Var"]))

# Results for the variables that are significant for either subset
kable_styling(kable(subset(adiv_cors_sep, Var %in% adiv_cors_sep_sigs), booktabs = TRUE,
  linesep = "", digits = 4, row.names = FALSE), font_size = 8)
```

Var	ShanCor	ShanP	InvSCor	InvSP	Set
acetic_acid	-0.3717	0.0052	-0.3233	0.0160	C_only
acetic_acid	-0.0175	0.8993	0.0001	0.9995	P_only
butyric_acid	-0.3165	0.0186	-0.2873	0.0334	C_only
butyric_acid	-0.1097	0.4254	-0.1203	0.3818	P_only
propionic_acid	-0.4445	0.0007	-0.3755	0.0047	C_only
propionic_acid	-0.0119	0.9313	0.0456	0.7410	P_only
Scalprotectin	-0.2191	0.1115	-0.2476	0.0711	C_only
Scalprotectin	-0.3075	0.0224	-0.2298	0.0914	P_only
SCXCL8	0.0427	0.7569	-0.0867	0.5291	C_only
SCXCL8	-0.2825	0.0366	-0.2453	0.0711	P_only
SNGAL	-0.4994	0.0001	-0.4213	0.0015	C_only
SNGAL	-0.2047	0.1496	-0.1497	0.2943	P_only
Szonulin	-0.3648	0.0062	-0.1952	0.1533	C_only
Szonulin	-0.2412	0.0760	-0.2473	0.0687	P_only
total_SCFAs	-0.4105	0.0019	-0.3513	0.0085	C_only
total_SCFAs	-0.0285	0.8364	-0.0210	0.8788	P_only

### 3.1.2.1 Fig S3

Make a figure summarizing the alpha diversity correlation results:

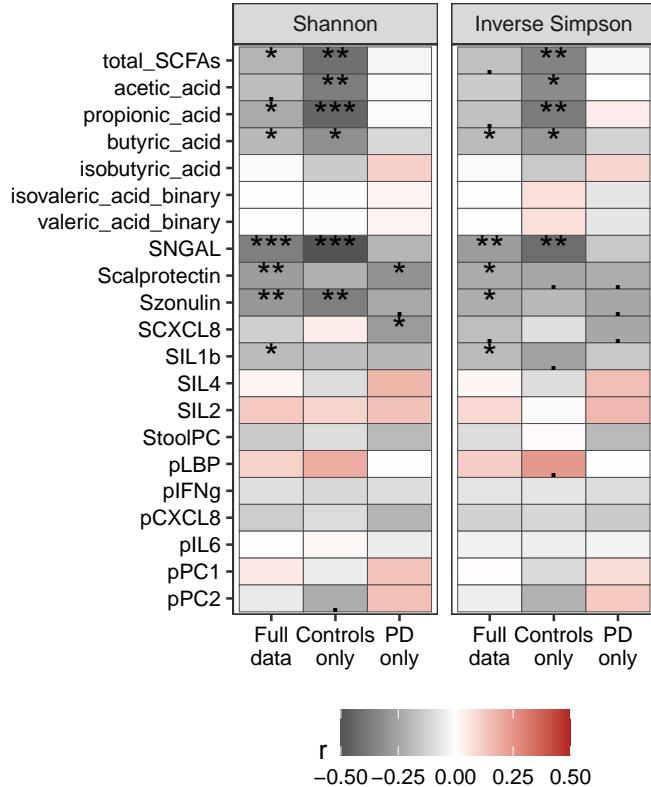

```
# Combine the results for full + subset
adiv_cors_full$Set <- "Full"
adiv_cors <- melt(rbind(adiv_cors_full, adiv_cors_sep))

# Split some variables
adiv_cors$Value <- sub(".*[nS]", "", adiv_cors$variable)
adiv_cors$Div <- sub("[PC] .*", "", adiv_cors$variable)
adiv_cors$Set <- factor(adiv_cors$Set, levels = c("Full", "C_only", "P_only"))

# Reorganize data.frame
adiv_cors_df <- dcast(adiv_cors, Var + Set + Div ~ Value)

# Reorder variables for nicer plotting
adiv_cors_df$Var <- factor(adiv_cors_df$Var, levels = rev(inf_scfa_vars))
adiv_cors_df$Div <- factor(adiv_cors_df$Div, levels = c("Shan", "InvS"))
levels(adiv_cors_df$Div) <- c("Shannon", "Inverse Simpson")
levels(adiv_cors_df$Set) <- c("Full\ndata", "Controls\nonly", "PD\nonly")

adiv_cors_plot <- ggplot(adiv_cors_df, aes(x = Set, y = Var, fill = Cor)) +
  geom_tile(color = "gray30") +
  theme_bw(base_size = 10) +
  facet_grid(~Div) +
  scale_fill_gradient2(low = "gray33", mid = "white", high = "firebrick",
                       name = "r", limits = c(-0.5, 0.5)) +
  geom_text(aes(label = stars.pval(P)), size = 5) +
  theme(legend.position = "bottom",
        axis.text = element_text(color = "black"),
        axis.title = element_blank(),
        panel.grid = element_blank())
adiv_cors_plot
```

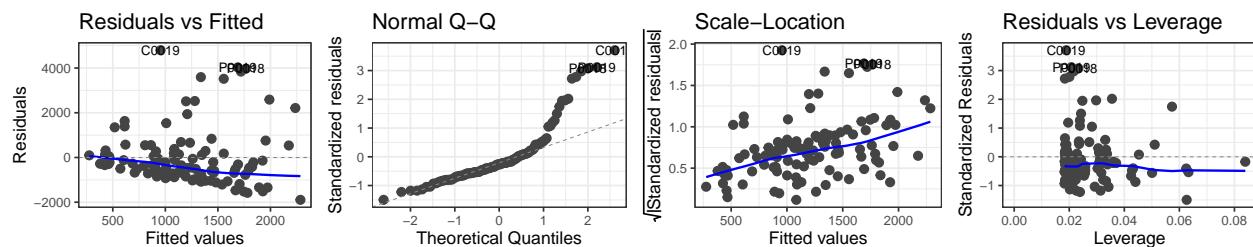

```
ggsave(adiv_cors_plot, filename = "Outputs/figS3_adiv_cors.pdf",
       width = maxwd*0.6, height = maxhi*0.6, units = "mm")
```

### 3.1.3 Corrected for PD vs C

To further explore the relationship of diversity, markers/SCFAs and PD, run linear regressions with the marker/SCFA as the dependent variable and diversity index + Group as explanatory variables. Test with a few example cases:

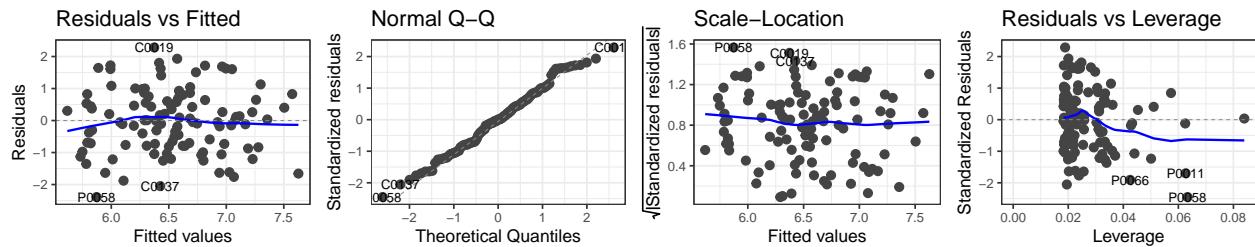

```
# Make model
lm_calpro_shan <- lm(Scalprotectin ~ Shannon + Group, pdcy_meta)

# Residual plots
autoplot(lm_calpro_shan, label.size = 2, nrow = 1) + theme_bw(base_size = 8)
```

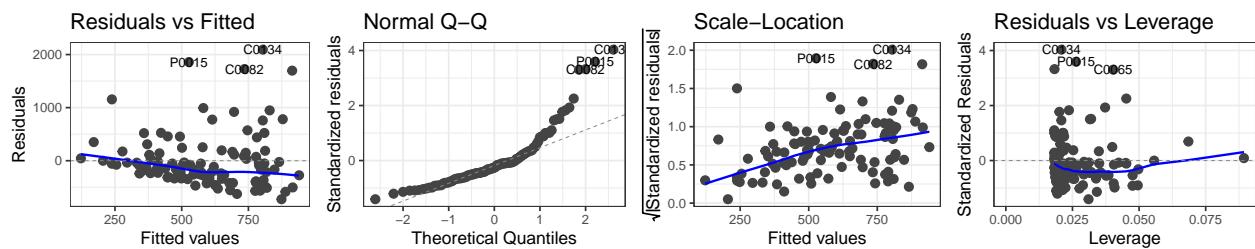

The diagnostic plots for the residuals imply heteroscedasticity. Log-transform calprotectin and plot again:

```
lm_shan_calpro_2 <- lm(log(Scalprotectin) ~ Shannon + Group, pdcy_meta)
autoplot(lm_shan_calpro_2, label.size = 2, nrow = 1) + theme_bw(base_size = 8)
```

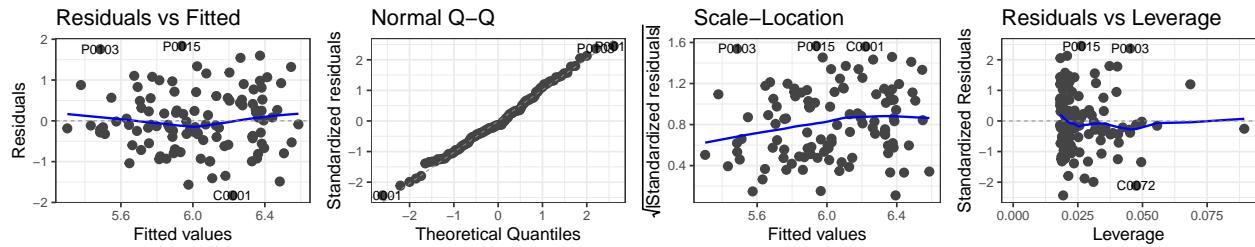

Run a similar test for Butyric acid ~ inverse Simpson + Group:

```
lm_buty_shan <- lm(butyric_acid ~ InvSimpson + Group, pdcy_meta)
autoplot(lm_buty_shan, label.size = 2, nrow = 1) + theme_bw(base_size = 8)
```

Try with log-transformed SCFA data:

```
lm_buty_shan2 <- lm(log(butyric_acid) ~ InvSimpson + Group, pdcy_meta)
autoplot(lm_buty_shan2, label.size = 2, nrow = 1) + theme_bw(base_size = 8)
```

Since the log-transformed response variables seem to provide better results, run all regression testing with log-transformed response variables. Test both diversity measures for the markers that were significant for full data for at least one measure in the previous regressions. Include additional correction for sex, since it seemed to have a strong effect on the PD-differences for some SCFAs and markers.

```
lm_vars <- as.character(unique(subset(adiv_cors,
                                         value < 0.05 & Value == "P" & Set == "Full")$Var))

pdc_div_lms <- as.data.frame(matrix(ncol = 4, nrow = 0))
colnames(pdc_div_lms) <- c("Model", "pValModel", "pValGroup", "pValDiv")

for(i in lm_vars){
  for(j in c("Shannon", "InvSimpson")){
    m <- as.formula(paste("log(", i, ")~sex+Group+", j))

### 3.1.3.2 Table S2B

```

# Fix variable labels
pdc_div_lms2$Model <- sub("\\\\(S", "\\\\(Stool ", sub("_acid", " acid", pdc_div_lms2$Model))
pdc_div_lms2$Variable <- capitalize(
  sub("\\\\.*", "", sub("log\\\\(", "", pdc_div_lms2$Model)))
pdc_div_lms2$DivIndex <- sub(".*\\\\/* ", "", pdc_div_lms2$Model)
pdc_div_lms2 <- pdc_div_lms2[, c("Model", "Variable", "DivIndex", "pValModel",
                                 "pValSex", "pValGroup", "pValDiv", "pValGroupDiv")]

# Export
write.csv(pdc_div_lms2, "Outputs/tableS2B.csv", row.names = FALSE)

```

### 3.1.4 Analyses with additional confounders

Finally, explore a few of the variable of interest ~ PD/control + diversity models in more detail:

#### 3.1.4.1 Calprotectin

Previous results for calprotectin models:

```

pdc_div_lms$pValGroupDiv <- NA
pdc_div_lm_all <- rbind(pdc_div_lms, pdc_div_lms2)

kable_styling(kable(pdc_div_lm_all[grep("calpro", pdc_div_lm_all$Model), c(1, 4:8)],
                   digits = 4, booktabs = TRUE, linesep = "", row.names = FALSE), font_size = 8)

```

Model		pValModel	pValSex	pValGroup	pValDiv	pValGroupDiv
log(Stool calprotectin) ~ sex + Group + Shannon		0	0.0208	0.0620	0.0000	NA
log(Stool calprotectin) ~ sex + Group + InvSimpson		0	0.0232	0.0327	0.0000	NA
log(Stool calprotectin) ~ sex + Group * Shannon		0	0.0196	0.3708	0.0133	0.4600
log(Stool calprotectin) ~ sex + Group * InvSimpson		0	0.0240	0.4905	0.0068	0.9875

Results were similar for the two indices; focus on inverse Simpson, the index with the lower  $p$ -value. The interaction was not significant for PD \* diversity. As alternatives, since there was a notable sex difference for calprotectin, test additional model with interaction:

```
print(anova(lm(log(Scalprotectin) ~ Group + sex + InvSimpson, data = pdcy_meta),
            lm(log(Scalprotectin) ~ Group + sex * InvSimpson, data = pdcy_meta)))
```

```
## Analysis of Variance Table
##
## Model 1: log(Scalprotectin) ~ Group + sex + InvSimpson
## Model 2: log(Scalprotectin) ~ Group + sex * InvSimpson
##   Res.Df   RSS Df Sum of Sq    F    Pr(>F)
## 1     105 102.249
## 2     104  90.482  1     11.767 13.525 0.0003747 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

In fact, it seems there could be an interaction for sex \* diversity; continue with that model. Potential additional confounders with  $p < 0.05$  for calprotectin based on the clinical variable correlations (Fig 2C):

```
calp_conf <- subset(meta_cors_st_P, variable == "Scalprotectin" &
                     value == TRUE & Set == "All subjects")$Confounder
calp_conf

## [1] History diabetes PD relative      RBDSQ
## 64 Levels: Age at stool collection BMI GDS15 ... UPDRS IV total
```

Test a model with all the potential confounders plus sex, then repeat with only significant confounders plus Group and inverse Simpson, and collect results into a table:

```
# Original model without any confounders
calp_m0 <- lm(log(Scalprotectin) ~ Group + sex * InvSimpson, pdcy_meta)
```

```
# All confounders
calp_m1 <- lm(log(Scalprotectin) ~ Group + sex * InvSimpson +
               history_diabetes + PD_relative + RBDSQ, pdcy_meta)
```

```
# Check results
```

```
summary(calp_m1)
```

```

            file = "Outputs/tableS2C.xlsx", open = FALSE)
```

### 3.1.4.2 Propionic acid

Previous results for propionic acid models:

```
kable_styling(kable(pdc_div_lm_all[grep("propionic", pdc_div_lm_all$Model), c(1, 4:8)],
                     digits = 4, booktabs = TRUE, linesep = "", row.names = FALSE), font_size = 8)
```

Model	pValModel	pValSex	pValGroup	pValDiv	pValGroupDiv
log(propionic acid) ~ sex + Group + Shannon	0.0057	0.5977	0.0196	0.0039	NA
log(propionic acid) ~ sex + Group + InvSimpson	0.0452	0.6625	0.0365	0.0501	NA
log(propionic acid) ~ sex + Group * Shannon	0.0012	0.6603	0.0117	0.0002	0.0197
log(propionic acid) ~ sex + Group * InvSimpson	0.0079	0.7396	0.0033	0.0020	0.0166

Focus on Shannon, which had the lower  $p$ -values. Which is better, model with an interaction or without?

```
print(anova(
  lm(log(propionic_acid) ~ sex + Group + Shannon, data = pdcy_meta),
  lm(log(propionic_acid) ~ sex + Group * Shannon, data = pdcy_meta)))

## Analysis of Variance Table
##
## Model 1: log(propionic_acid) ~ sex + Group + Shannon
## Model 2: log(propionic_acid) ~ sex + Group * Shannon
##   Res.Df   RSS Df Sum of Sq    F Pr(>F)
## 1     106 35.901
## 2     105 34.080  1     1.8212 5.6112 0.01967 *
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

The model with an interaction was better, so continue with that, and add correction for confounding variables. Potential confounders with  $p < 0.05$  for propionic acid from the clinical variable correlations (Fig 2A):

```
prop_conf <- subset(meta_cors_sc_P, variable == "propionic_acid" &
                      value == TRUE & Set == "All subjects")$Confounder
prop_conf

## [1] GDS15                  Medication ACE AT1      Medication statin
## [4] NMSS total              Rome III 9-15 sum score
## 64 Levels: Age at stool collection BMI GDS15 ... UPDRS IV total
```

Test a model with all potential confounders plus sex, then repeat with significant confounders plus Group and inverse Simpson:

```
# Original model
prop_m0 <- lm(log(propionic_acid) ~ sex + Group * Shannon, pdcy_meta)

# All confounders
prop_m1 <- lm(log(propionic_acid) ~ sex + Group * Shannon + GDS15 + meds_ACE_AT1 +
               meds_statin + NMSS_total + Rome_III_constip_defec_sumscore_9.15,
               pdcy_meta)

# Check results
summary(prop_m1)
```

```

## Call:
## lm(formula = log(propionic_acid) ~ sex + Group * Shannon + GDS15 +

```

### 3.2 Beta diversity

Test beta diversity differences based on Bray-Curtis dissimilarities of subsampled data with adonis (PERMANOVA). This test does not accept missing values, so drop subjects with NAs from the comparisons for each variable.

#### 3.2.1 Full data (PD + C together)

```
# Run adonis for each variable separately
bdiv_all <- list()

for(i in inf_scfa_vars){
  phy <- subset_samples(pdcy_phy, !is.na(sample_data(pdcy_phy)[[i]]))
  rar <- rarefy_even_depth(phy, rngseed = 1942890)
  dis <- vegdist(as.data.frame(t(as.matrix(otu_table(rar)))))
  bdiv_all[[i]] <- adonis(as.formula(paste("dis ~", i)),
                           data = as(sample_data(rar), "data.frame"),
                           permutations = 9999)$aov.tab
}

# Grab p-values
bdiv_all_p <- sapply(inf_scfa_vars, function(x) bdiv_all[[x]][["Pr(>F)"]][1])
```

```
# Make data frame
bdiv_all_p <- data.frame(Variable = names(bdiv_all_p),
                           pVar = bdiv_all_p)
```

Significant results for these comparisons:

```
kable(subset(bdiv_all_p, pVar < 0.05), row.names = FALSE, booktabs = TRUE,
      linesep = "", digits = 3)
```

Variable	pVar
total_SCFAs	0.000
acetic_acid	0.000
propionic_acid	0.000
butyric_acid	0.000
SNGAL	0.008
Szonulin	0.001
SIL2	0.030
StoolPC	0.016

### 3.2.2 Corrected for PD vs control

Run adonis2 models with the immune marker/SCFA variables corrected for Group, since based on previous analyses, there is a significant beta diversity difference between PD and control.

```
# Run adonis for each variable
bdiv_pdc <- list()

for(i in inf_scfa_vars){
  phy <- subset_samples(pdphy, !is.na(sample_data(pdphy)[[i]]))
  rar <- rarefy_even_depth(phy, rngseed = 1942890)
  dis <- vegdist(as.data.frame(t(as.matrix(otu_table(rar)))))
  bdiv_pdc[[i]] <- adonis2(as.formula(paste("dis ~ Group + ", i)),
                            data = as(sample_data(rar), "data.frame"),
                            permutations = 9999, by = "margin")["Pr(>F)"]
}

# Grab p-values into data frame
bdiv_pdc_p <- data.frame(
  Var = inf_scfa_vars,
  pGroup = sapply(inf_scfa_vars, function(x) bdiv_pdc[[x]][1,]),
  pVar = sapply(inf_scfa_vars, function(x) bdiv_pdc[[x]][2,]))
```

Variables that were significant when corrected for Group:

```
kable(subset(bdiv_pdc_p, pVar < 0.05), row.names = FALSE, booktabs = TRUE,
      linesep = "", digits = 3)
```

Var	pGroup	pVar
total_SCFAs	0.001	0.000
acetic_acid	0.000	0.000
propionic_acid	0.001	0.000
butyric_acid	0.002	0.000
SNGAL	0.001	0.007
Szonulin	0.000	0.000
SIL2	0.000	0.030
StoolPC	0.000	0.022

### 3.2.3 Control only / PD only

As an alternative PD/control comparison, run tests separately for PD-only and control-only subsets.

#### 3.2.3.0.1 C-only

```
bdiv_c <- list()

for(i in inf_scfa_vars){
  phy <- subset_samples(pdcy_phy_C, !is.na(sample_data(pdcy_phy_C)[[i]]))
  rar <- rarefy_even_depth(phy, rngseed = 3656154)
  dis <- vegdist(as.data.frame(t(as.matrix(otu_table(rar)))))
  bdiv_c[[i]] <- adonis(as.formula(paste("dis ~", i)),
                         data = as(sample_data(rar), "data.frame"),
                         permutations = 9999)$aov.tab
}

# Grab p-values
bdiv_c_p <- sapply(inf_scfa_vars, function(x) bdiv_c[[x]][["Pr(>F)"]][1])

# Make data frame
bdiv_c_p <- data.frame(Var = names(bdiv_c_p),
                       pVar = bdiv_c_p)
```

#### 3.2.3.0.2 PD-only

```
bdiv_pd <- list()

for(i in inf_scfa_vars){
  phy <- subset_samples(pdcy_phy_P, !is.na(sample_data(pdcy_phy_P)[[i]]))
  rar <- rarefy_even_depth(phy, rngseed = 2160957)
  dis <- vegdist(as.data.frame(t(as.matrix(otu_table(rar)))))
  bdiv_pd[[i]] <- adonis(as.formula(paste("dis ~", i)),
                         data = as(sample_data(rar), "data.frame"),
                         permutations = 9999)$aov.tab
}

# Grab p-values
bdiv_pd_p <- sapply(inf_scfa_vars, function(x) bdiv_pd[[x]][["Pr(>F)"]][1])

# Make data frame
bdiv_pd_p <- data.frame(Var = names(bdiv_pd_p),
                        pVar = bdiv_pd_p)
```

Results with a significant uncorrected  $p$ -value in either the C-only or PD-only comparisons:

```
bdiv_pdc_separated <- data.frame(Var = rownames(bdiv_c_p),
                                 pVar_C = bdiv_c_p[, 2],
                                 pVar_P = bdiv_pd_p[, 2])

kable(bdiv_pdc_separated[rowSums(bdiv_pdc_separated[, 2:3] < 0.05) > 0,],
      booktabs = TRUE, linesep = "", digits = 3, row.names = FALSE)
```

Var	pVar_C	pVar_P
total_SCFAs	0.000	0.066
acetic_acid	0.000	0.275
propionic_acid	0.001	0.217
butyric_acid	0.000	0.004
SNGAL	0.004	0.307
Szonulin	0.008	0.021

### 3.2.4 Analyses with additional confounders

Run the tests with additional correction for sex and the main beta diversity confounders from the follow-up microbiome article (Aho et al. 2019).

```
# Run adonis for each variable
bdiv_pdc_conf <- list()

for(i in inf_scfa_vars){
  phy <- subset_samples(pdcy_phy, !is.na(sample_data(pdcy_phy)[[i]]))
  rar <- rarefy_even_depth(phy, rngseed = 1942890)
  dis <- vegdist(as.data.frame(t(as.matrix(otu_table(rar)))))
  bdiv_pdc_conf[[i]] <- adonis2(as.formula(
    paste("dis ~ Group + sex + Rome_III_constip_defecsumscore_9.15 + BMI +", i)),
    data = as(sample_data(rar), "data.frame"),
    permutations = 9999, by = "margin")["Pr(>F)"]
}

# Grab p-values into data frame
bdiv_pdc_conf_p <- data.frame(
  Var = inf_scfa_vars,
  pGroup = sapply(inf_scfa_vars, function(x) bdiv_pdc_conf[[x]][1,]),
  pVar = sapply(inf_scfa_vars, function(x) bdiv_pdc_conf[[x]][5,]))
```

Significant results:

```
kable(subset(bdiv_pdc_conf_p, pVar < 0.05),
      row.names = FALSE, booktabs = TRUE, linesep = "", digits = 3)
```

Var	pGroup	pVar
total_SCFAs	0.008	0.000
acetic_acid	0.008	0.001
propionic_acid	0.008	0.000
butyric_acid	0.016	0.000
SNGAL	0.031	0.005
Szonulin	0.008	0.002
SIL2	0.006	0.030
StoolPC	0.008	0.023

### 3.2.4.1 Table S3A

Collect all the results from the above comparisons into one data frame and export:

```
bdiv_combo <- data.frame(
  Variable = bdiv_all_p$Variable,
  'p (full data)' = bdiv_all_p$pVar,
  'p (control only)' = bdiv_pdc_separated$pVar_C,
  'p (PD only)' = bdiv_pdc_separated$pVar_P,
  'p (PD/C corrected)' = bdiv_pdc_p$pVar,
  'p (PD/C + confounder corrected)' = bdiv_pdc_conf_p$pVar,
  check.names = FALSE
)

# Variables with anything significant?
kable_styling(kable(bdiv_combo[rowSums(bdiv_combo[, 2:5] < 0.05) > 0,], booktabs = TRUE,
  linesep = "", digits = 3, row.names = FALSE), font_size = 8)
```

Variable	p (full data)	p (control only)	p (PD only)	p (PD/C corrected)	p (PD/C + confounder corrected)
total_SCFAs	0.000	0.000	0.066	0.000	0.000
acetic_acid	0.000	0.000	0.275	0.000	0.001
propionic_acid	0.000	0.001	0.217	0.000	0.000
butyric_acid	0.000	0.000	0.004	0.000	0.000
SNGAL	0.008	0.004	0.307	0.007	0.005
Szonulin	0.001	0.008	0.021	0.000	0.002
SIL2	0.030	0.479	0.076	0.030	0.030
StoolPC	0.016	0.598	0.054	0.022	0.023

```
# Fix variable labels
bdiv_combo$Variable <- sub(" tool", " ", varLabelFix(bdiv_combo$Variable))

# Export the full combined table
write.csv(bdiv_combo, "Outputs/tableS3A.csv", row.names = FALSE)
```

### 3.2.4.2 Fig S4

Plot the most interesting cases with variable values split into two categories by median for better visualization:

```
# Subsample to the same number of reads
pdcy_phy_R <- rarefy_even_depth(pdphy, rngseed = 1942890)

# Calculate ordination
mds_all <- metaMDS(as.data.frame(t(as.matrix(otu_table(pdphy_R)))), try = 500, trace = FALSE)

# Get points
mds_all_df <- data.frame(NMDS1 = mds_all$points[,1],
  NMDS2 = mds_all$points[,2],
  as(sample_data(pdphy_R), "data.frame"))

# Custom plot function
bdiv_plot_2cat <- function(df, var, cols, u){
  var_bin <- factor(df[[var]] > median(df[[var]]), na.rm = TRUE)
  levels(var_bin) <- substitute(c(
    paste(var, '\u2264', round(median(df[[var]]), na.rm = TRUE), digits = 1), u),
    paste(var, ">", round(median(df[[var]]), na.rm = TRUE), digits = 1), u)))
```

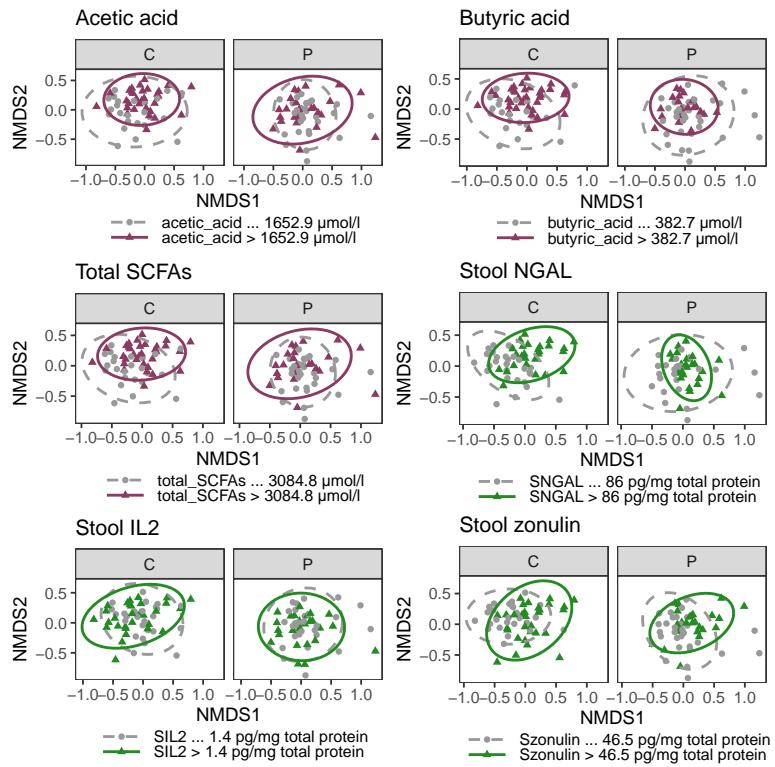

```

df_temp <- data.frame(df, var_bin = var_bin)

p <- ggplot(subset(df_temp, !is.na(var_bin)),
            aes(x = NMDS1, y = NMDS2,
                color = var_bin, linetype = var_bin, shape = var_bin)) +
  geom_point(size = 0.8) +
  theme_bw(base_size = 7) +
  coord_fixed() +
  facet_grid(~Group) +
  ggtitle(var) +
  stat_ellipse(level = 0.95, lwd = 0.5, aes(color = var_bin)) +
  scale_color_manual(values = cols, name = NULL) +
  scale_linetype_manual(values = c(2, 1), name = NULL) +
  scale_shape_manual(values = c(16, 17), name = NULL) +
  guides(color = guide_legend(nrow = 2),
         linetype = guide_legend(nrow = 2),
         shape = guide_legend(nrow = 2)) +
  theme(panel.grid = element_blank(),
        legend.position = "bottom",
        legend.margin = margin(t = -2, b = -3, unit = "mm"),
        legend.key.height = unit(2, "mm"),
        plot.margin = unit(c(-7, 1, -5, 1), "mm"),
        plot.title = element_text(size = 8))
rm(df_temp)
return(p)
}

# Draw plots
bdiv_plots <- arrangeGrob(
  bdiv_plot_2cat(mds_all_df, "acetic_acid", c("gray60", "hotpink4"),
                 c('\u00B5mol/l')) + ggtitle("Acetic acid"),
  bdiv_plot_2cat(mds_all_df, "butyric_acid", c("gray60", "hotpink4"),

                 "pg/mg total protein") + ggtitle("Stool IL2"),
  bdiv_plot_2cat(mds_all_df, "Sztonulin", c("gray60", "forestgreen"),
                 "pg/mg total protein") + ggtitle("Stool zonulin"),
  ncol = 2)
grid.arrange(bdiv_plots)

```

```
ggsave(bdiv_plots, filename = "Outputs/figS4_bdivs.pdf",
       device = cairo_pdf, width = 100, height = 120, units = "mm")
```

### 3.2.5 Interaction effects

Test for interactions between Group and markers/SCFAs:

```
bdiv_pdc_i <- list()

for(i in inf_scfa_vars){
  phy <- subset_samples(pdcy_phy, !is.na(sample_data(pdcy_phy)[[i]]))
  rar <- rarefy_even_depth(phy, rngseed = 1942890)
  dis <- vegdist(as.data.frame(t(as.matrix(otu_table(rar)))))
  bdiv_pdc_i[[i]] <- adonis2(as.formula(paste("dis ~ Group * ", i)),
                               data = as(sample_data(rar), "data.frame"),
                               permutations = 9999)[["Pr(>F)"]]
}

# Grab p-values into data frame
bdiv_pdc_i_p <- data.frame(
  Var = inf_scfa_vars,
  pGroup = sapply(inf_scfa_vars, function(x) bdiv_pdc_i[[x]][1,]),
  pVar = sapply(inf_scfa_vars, function(x) bdiv_pdc_i[[x]][2,]),
  pInteraction = sapply(inf_scfa_vars, function(x) bdiv_pdc_i[[x]][3,]))
```

Any significant results?

```
kable(subset(bdiv_pdc_i_p, pInteraction < 0.1),
      row.names = FALSE, booktabs = TRUE, linesep = "", digits = 3)
```

Var	pGroup	pVar	pInteraction
pIL6	0	0.409	0.035

Same, but with variables of interest split to binary by median (as in Figure S3 above):

```
# Make a df of binary variables (with new versions of the two already binary SCFA vars)
bd_meta_bin <- sapply(
  sub("_binary", "", inf_scfa_vars),
  function (x) sample_data(pdcy_phy)[[x]] >
    median(sample_data(pdcy_phy)[[x]], na.rm = TRUE))
colnames(bd_meta_bin) <- paste(colnames(bd_meta_bin), "2cat", sep = "_")

pdcy_phy_bd <- pdcy_phy
sample_data(pdcy_phy_bd) <- cbind(sample_data(pdcy_phy_bd), bd_meta_bin)

bdiv_pdc_i2 <- list()

for(i in colnames(bd_meta_bin)){
  phy <- subset_samples(pdcy_phy_bd, !is.na(sample_data(pdcy_phy_bd)[[i]]))
  rar <- rarefy_even_depth(phy, rngseed = 1942890)
  dis <- vegdist(as.data.frame(t(as.matrix(otu_table(rar)))))
  bdiv_pdc_i2[[i]] <- adonis2(as.formula(paste("dis ~ Group * ", i)),
                                data = as(sample_data(rar), "data.frame"),
                                permutations = 9999)["Pr(>F)"]
}

# Grab p-values into data.frame form
bdiv_pdc_i2_p <- data.frame(
  Var = colnames(bd_meta_bin),
  pGroup = sapply(colnames(bd_meta_bin), function(x) bdiv_pdc_i2[[x]][1,]),
  pVar = sapply(colnames(bd_meta_bin), function(x) bdiv_pdc_i2[[x]][2,]),
  pInteraction = sapply(colnames(bd_meta_bin), function(x) bdiv_pdc_i2[[x]][3,]))
```

Any significant results?

```
kable(subset(bdiv_pdc_i2_p, pInteraction < 0.1),
      row.names = FALSE, booktabs = TRUE, linesep = "", digits = 3)
```

Var	pGroup	pVar	pInteraction
butyric_acid_2cat	0	0.000	0.040
SNGAL_2cat	0	0.000	0.062
Szonulin_2cat	0	0.001	0.038

### 3.2.5.1 Table S3B

Combine and export the interaction results.

```
# Combine result data frames
bdiv_interact_res <- cbind(bdiv_pdc_i_p, bdiv_pdc_i2_p)

# Fix variable labels
bdiv_interact_res$Var <- sub(" tool", " ", varLabelFix(bdiv_interact_res$Var))

# Export
write.csv(bdiv_interact_res, "Outputs/tableS3B.csv", row.names = FALSE)
```

### 3.3 Enterotypes

Look for differences in levels of variables of interest in relation to [enterotypes](#). Based on the previous publication on this data, the distributions of enterotypes in the PD and control groups were slightly different, mainly with more PD subjects in the *Firmicutes* and less in the *Prevotella* enterotype. In this specific subset, the numbers were the following:

```
kable(table(pdcy_meta$Enterotype, pdcy_meta$Group), booktabs = TRUE)
```

	C	P
ET_B	8	8
ET_F	25	35
ET_P	22	10

This difference in distributions was statistically significant (Fisher's exact test  $p = 0.045$ ).

Run tests (Kruskal-Wallis rank sum test) for significant differences in concentrations of stool and plasma markers and SCFAs between enterotypes for

1. full data
2. control subjects only
3. PD patients only,

and collect the results into one data frame:

```
# Generic testing function with Kruskal-Wallis
kwTestET <- function(df){
  res <- data.frame(Variable = inf_scfa_vars,
                     pVal = sapply(inf_scfa_vars, function(x)
                                   kruskal.test(as.formula(paste(x, "~Enterotype")), df)$p.value))
  res$pAdj <- c(
    p.adjust(res[scfa_vars, "pVal"], method = "fdr"),
    p.adjust(res[infs_vars, "pVal"], method = "fdr"),
    p.adjust(res[infp_vars, "pVal"], method = "fdr"))
  return(res)
}

# Full data
kw_et <- kwTestET(pdcy_meta)
# Only control subjects
kw_et_c <- kwTestET(subset(pdcy_meta, Group == "C"))
# Only PD
kw_et_p <- kwTestET(subset(pdcy_meta, Group == "P"))

# Combine results
kw_et_combo <- data.frame(Variable = kw_et$Variable,
                           pVal_all = kw_et$pVal,
                           pAdj_all = kw_et$pAdj,
                           pVal_C = kw_et_c$pVal,
                           pAdj_C = kw_et_c$pAdj,
                           pVal_PD = kw_et_p$pVal,
                           pAdj_PD = kw_et_p$pAdj)
```

#### 3.3.0.1 Table S4

Significant results from the above comparisons:

```
# Variables with p < 0.05 for at least one of the three datasets
kable(kw_et_combo[rowSums(kw_et_combo[, c(2, 4, 6)] < 0.05) > 0, ],
      booktabs = TRUE, linesep = "", digits = 3, row.names = FALSE)
```

Variable	pVal_all	pAdj_all	pVal_C	pAdj_C	pVal_PD	pAdj_PD
propionic_acid	0.044	0.159	0.348	0.770	0.161	0.377
butyric_acid	0.045	0.159	0.423	0.770	0.013	0.093
SNGAL	0.001	0.008	0.002	0.008	0.419	0.936
Szonulin	0.114	0.376	0.000	0.003	0.634	0.936

```
# Fix variable names for export
kw_et_combo$Variable <- varLabelFix(kw_et_combo$Variable)

# Export the full table
write.csv(kw_et_combo, "Outputs/tableS4.csv", row.names = FALSE)
```

Run post-hoc tests (pairwise Wilcoxon rank sum test) to see which pairs of enterotypes differ:

### 3.3.0.1.1 NGAL

```
et_ngal_c <- as.data.frame(
  pairwise.wilcox.test(x = subset(pdcy_meta, Group == "C")$SNGAL,
                        g = subset(pdcy_meta, Group == "C")$Enterotype)$p.value)
et_ngal_c$Comp <- rownames(et_ngal_c)
et_ngal_c <- melt(et_ngal_c)
colnames(et_ngal_c) <- c("ET1", "ET2", "pVal")

kable(subset(et_ngal_c, !is.na(pVal)), booktabs = TRUE, digits = 3, row.names = FALSE)
```

ET1	ET2	pVal
ET_F	ET_B	0.204
ET_P	ET_B	0.001
ET_P	ET_F	0.027

### 3.3.0.1.2 Zonulin

```
et_zon_c <- as.data.frame(
  pairwise.wilcox.test(x = subset(pdcy_meta, Group == "C")$Szonulin,
                        g = subset(pdcy_meta, Group == "C")$Enterotype)$p.value)
et_zon_c$Comp <- rownames(et_zon_c)
et_zon_c <- melt(et_zon_c)
colnames(et_zon_c) <- c("ET1", "ET2", "pVal")

kable(subset(et_zon_c, !is.na(pVal)), booktabs = TRUE, digits = 3, row.names = FALSE)
```

ET1	ET2	pVal
ET_F	ET_B	0.374
ET_P	ET_B	0.002
ET_P	ET_F	0.002

### 3.3.0.1.3 Butyric acid

```
et_but_p <- as.data.frame(
  pairwise.wilcox.test(x = subset(pdcy_meta, Group == "P")$butyric_acid,
```

```

g = subset(pdcy_meta, Group == "P")$Enterotype$p.value)
et_but_p$Comp <- rownames(et_but_p)
et_but_p <- melt(et_but_p)
colnames(et_but_p) <- c("ET1", "ET2", "pVal")
kable(subset(et_but_p, !is.na(pVal)), booktabs = TRUE, digits = 3, row.names = FALSE)

```

ET1	ET2	pVal
ET_F	ET_B	0.939
ET_P	ET_B	0.017
ET_P	ET_F	0.017

### 3.3.0.2 Fig S5

Combine the results, make a plot and export:

```

# Handmade DF for p-value annotations
et_pvals <- rbind(
  data.frame(subset(et_but_p, pVal < 0.05),
             Group = "P",
             variable = "butyric_acid"),
  data.frame(subset(et_ngal_c, pVal < 0.05),
             Group = "C",
             variable = "SNGAL"),
  data.frame(subset(et_zon_c, pVal < 0.05),
             Group = "C",
             variable = "Sztonulin"))

et_pvals$stars <- stars.pval(et_pvals$pVal)

et_plots

```

```

ggsave(et_plots, filename = "Outputs/figS5_enterotypes.pdf",
       width = maxwd/2, height = maxhi/2, units = "mm")

```

### 3.4 Differential abundance with DESeq2

Look for bacterial genera and families associated with specific markers/SCFAs with DESeq2, focusing on variables that were particularly interesting based on the other comparisons: stool calprotectin, NGAL, zonulin, and the three most common SCFAs. Run the comparisons in four different ways:

1. Taxon ~ variable, full data
2. Taxon ~ variable + sex + Rome III 9-15 score + PD/C, full data
3. Taxon ~ variable, control subjects only
4. Taxon ~ variable, PD patients only

Set up data and functions for testing:

```

# Functions

# One variable, Taxon ~ variable of interest
ds2_1var <- function(phylObj, v){
  phylObj <- prune_samples(as.vector(!is.na(sample_data(phylObj)[,v])), phylObj)
  ds <- phyloseq_to_deseq2(phylObj, as.formula(paste(~", v)))
}

```

```

ds <- DESeq(ds, fitType = "parametric", sfType = "poscounts")
dsres <- cbind(data.frame(results(ds)), as(tax_table(phyloObj), "matrix"))

return(dsres)
}

# Confounder-corrected:
# Taxon ~ variable of interest + sex + Rome III score + PD/control
# (grabbing results for the variable of interest only!)
ds2_1var_pdc <- function(phyloObj, v){
  phyloObj <- prune_samples(as.vector(!is.na(sample_data(phyloObj)[,v])), phyloObj)
  ds <- phyloseq_to_deseq2(phyloObj, as.formula(
    paste("~", v, "+ sex + Rome_III_constip_defec_sumscore_9.15 + Group")))
  ds <- DESeq(ds, fitType = "parametric", sfType = "poscounts")
  dsres <- cbind(data.frame(results(ds, name = v)),
                 as(tax_table(phyloObj), "matrix"))

  return(dsres)
}

# Phyloseq objects

# Function for trimming rare taxa and unclassifieds from the phyloseq objects
ds2trim <- function(phyloIn){
  lv <- tail(colnames(tax_table(phyloIn)), n = 1)
  phyloIn <- filter_taxa(phyloIn, function(x) sum(x > 5) > nsamples(pdcy_phy)/2,
                         prune = TRUE)
  prune_taxa(as.vector(tax_table(phyloIn)[, lv] != "unclassified"), phyloIn)
}

# Full data
pdcy_phy_gen_trim <- ds2trim(pdcy_phy_gen)
pdcy_phy_fam_trim <- ds2trim(pdcy_phy_fam)

# Make the PD-only and C-only subsets by subsetting these objects,
# so that all comparisons have the same set of taxa:

# Controls only
pdcy_phy_C_gen_trim <- subset_samples(pdcy_phy_gen_trim, Group == "C")
pdcy_phy_C_fam_trim <- subset_samples(pdcy_phy_fam_trim, Group == "C")

# PD only
pdcy_phy_P_gen_trim <- subset_samples(pdcy_phy_gen_trim, Group == "P")
pdcy_phy_P_fam_trim <- subset_samples(pdcy_phy_fam_trim, Group == "P")

```

### 3.4.1 SCFAs

Run comparisons for SCFAs:

```

# Variables of interest
da_scfa_vars <- c("acetic_acid", "butyric_acid", "propionic_acid")

# Family level comparisons
fam_scfa <- do.call("rbind",

```

```

c(lapply(da_scfa_vars,
          function(x) data.frame(ds2_1var(pdcy_phy_fam_trim, x),
                                 SCFA = x,
                                 Subset = "all")),
  lapply(da_scfa_vars,
          function(x) data.frame(ds2_1var_pdc(pdcy_phy_fam_trim, x),
                                 SCFA = x,
                                 Subset = "pdc")),
  lapply(da_scfa_vars,
          function(x) data.frame(ds2_1var(pdcy_phy_C_fam_trim, x),
                                 SCFA = x,
                                 Subset = "C")),
  lapply(da_scfa_vars,
          function(x) data.frame(ds2_1var(pdcy_phy_P_fam_trim, x),
                                 SCFA = x,
                                 Subset = "P")))

# Genus level comparisons
gen_scfa <- do.call("rbind",
                      c(lapply(da_scfa_vars,
                                function(x) data.frame(ds2_1var(pdcy_phy_gen_trim, x),
                                                       SCFA = x,
                                                       Subset = "all")),
                        lapply(da_scfa_vars,
                                function(x) data.frame(ds2_1var_pdc(pdcy_phy_gen_trim, x),
                                                       SCFA = x,
                                                       Subset = "pdc")),
                        lapply(da_scfa_vars,
                                function(x) data.frame(ds2_1var(pdcy_phy_C_gen_trim, x),
                                                       SCFA = x,
                                                       Subset = "C")),
                        lapply(da_scfa_vars,
                                function(x) data.frame(ds2_1var(pdcy_phy_P_gen_trim, x),
                                                       SCFA = x,
                                                       Subset = "P"))))

```

Collect and reorganize results:

```

# List taxa significant in any comparison
fam_scfa_res_df <- subset(fam_scfa,
                           Family %in% unique(subset(fam_scfa, padj < 0.05)$Family))
fam_scfa_res_df$Taxon <- fam_scfa_res_df$Family
fam_scfa_res_df$Genus <- NA

gen_scfa_res_df <- subset(gen_scfa,
                           Genus %in% unique(subset(gen_scfa, padj < 0.05)$Genus))
gen_scfa_res_df$Taxon <- gen_scfa_res_df$Genus

# Combined data frame
scfa_res_df <- rbind(data.frame(fam_scfa_res_df, Level = "Family"),
                      data.frame(gen_scfa_res_df, Level = "Genus"))

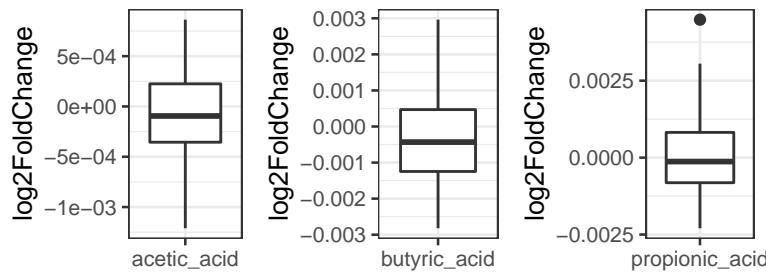

# Reorganize for plotting
scfa_res_df_m <- melt(scfa_res_df)

```

```
scfa_res_df_c <- dcast(scfa_res_df_m, SCFA + Taxon + Subset + Level ~ variable)
scfa_res_df_c$pStar <- stars.pval(scfa_res_df_c$padj)
```

Check for outlierish log2 fold changes:

```
# Check the spreads of values for the log2 fc
do.call("grid.arrange",
  c(lapply(da_scfa_vars, function(x)
    ggplot(subset(scfa_res_df_c, SCFA == x),
           aes(x = SCFA, y = log2FoldChange)) +
      geom_boxplot() +
      xlab(NULL) +
      theme_bw(base_size = 10)), nrow = 1))
```

No major outliers. Export the final table:

### 3.4.1.1 Table S5A

```
# Rename the group levels
scfa_res_df_c$Subset <- factor(scfa_res_df_c$Subset, levels = c("all", "pdc", "C", "P"))
levels(scfa_res_df_c$Subset) <- c("full data",
                                    "full data, corrected for PD/C and confounders",

### 3.4.1.3 Fig S6

Scatterplots of the most interesting taxa from the results.

```
# Set up a relative abundance data.frame
ra_df_gen <- t(prop.table(as(otu_table(pdcy_phy_gen), "matrix"), 2)*100)
ra_df <- cbind(ra_df_gen, sample_data(pdcy_phy_gen)[, c("Group", inf_scfa_vars)])

# Remove the doubled "unclassified" column
ra_df <- ra_df[, -(grep("unclassified", colnames(ra_df)))] 

# Scatterplot function for relative abundances
ra_scatter <- function(df, xvar, taxon){
  ggplot(df, aes_string(x = xvar, y = taxon)) +
    geom_point(size = 0.75) +
    theme_bw(base_size = 8) +
    facet_grid(~Group) +
    ylab("Relative abundance (%)") +
    ggtitle(taxon) +
    theme(panel.grid = element_blank(),
          axis.text = element_text(color = "black"),
          plot.title = element_text(face = "italic"))
}
```

Since the three SCFAs had overall similar patterns for the taxa, only plot each taxon once:

```

# Significant taxa for butyric acid
buty_sigs <- as.character(unique(
  subset(scfa_res_df_c_gen, SCFA == "Butyric acid" & padj < 0.1)$Taxon))

# Significant taxa for acetic acid that are not on the butyric acid list
acet_sigs <- setdiff(as.character(unique(
  subset(scfa_res_df_c_gen, SCFA == "Acetic acid" & padj < 0.1)$Taxon)), buty_sigs)

# Any significant taxa for propionic acid not on the butyric acid or acetic acid list?
setdiff(setdiff(as.character(unique(
  subset(scfa_res_df_c_gen, SCFA == "Propionic acid" & padj < 0.1)$Taxon)),
  buty_sigs), acet_sigs)

## character(0)

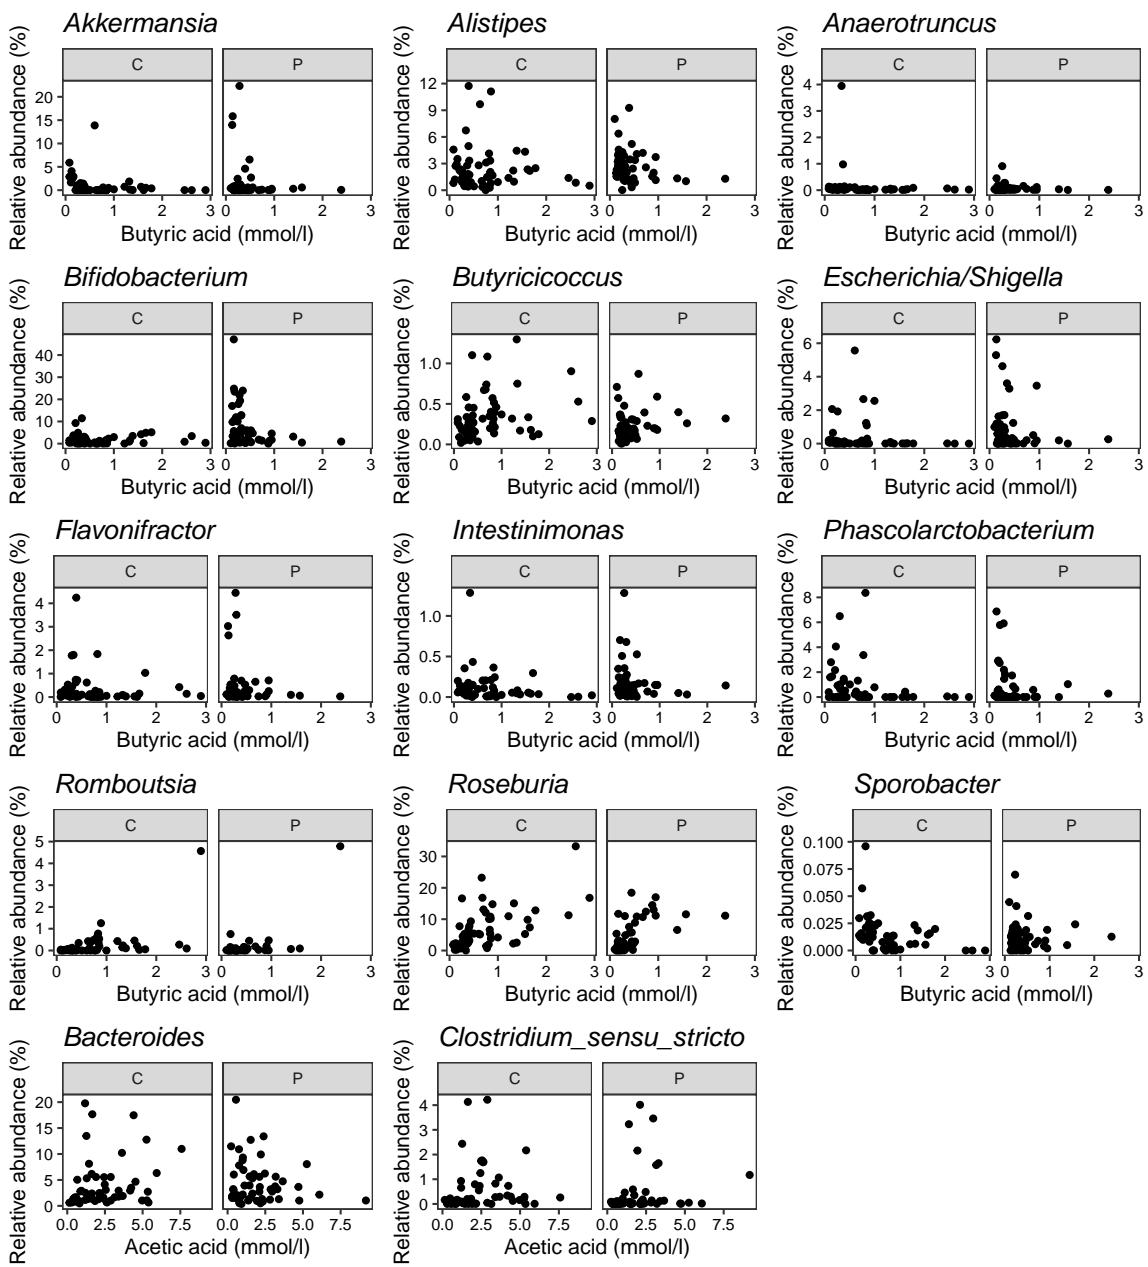

# Fix the problematically named Escherichia/Shigella
buty_sigs[grep("Escher", buty_sigs)] <- "`Escherichia/Shigella`"
# Fix the spaces in Clostridium sensu stricto
acet_sigs[grep("Clost", acet_sigs)] <- gsub(" ", "_", acet_sigs[grep("Clost", acet_sigs)])

# Plot
scfa_da_scatters <- c(
  lapply(buty_sigs, function(x)
    ra_scatter(ra_df, "butyric_acid/1000", x) +
    xlab("Butyric acid (mmol/l"))),
  lapply(acet_sigs, function(x)
    ra_scatter(ra_df, "acetic_acid/1000", x) +
    xlab("Acetic acid (mmol/l)))))

# Fix the title for 'Escherichia/Shigella'
scfa_da_scatters[[grep("Escher", buty_sigs)]] <-
  scfa_da_scatters[[grep("Escher", buty_sigs)]] +
  ggtitle("Escherichia/Shigella")

# Arrange plots
scfa_da_scatters <- do.call(arrangeGrob, c(scfa_da_scatters, ncol = 3))
grid.arrange(scfa_da_scatters)

```

```
# Export
ggsave(scfa_da_scatters,
       filename = "Outputs/figS6_diffabund_scatters_scfas.pdf",
       width = maxwd, height = maxhi*0.9, units = "mm")
```

### 3.4.2 Inflammatory markers

Run comparisons for stool markers:

```
# Variables of interest
da_inf_vars <- c("SNGAL", "Sztonulin", "Scalprotectin")

# Family level comparisons
fam_inf <- do.call("rbind",
                    c(lapply(da_inf_vars,
```

```

        function(x) data.frame(ds2_1var(pdcy_phy_fam_trim, x),
                                Marker = x,
                                Subset = "all")),
    lapply(da_inf_vars,
          function(x) data.frame(ds2_1var_pdc(pdcy_phy_fam_trim, x),
                                Marker = x,
                                Subset = "pdc")),
    lapply(da_inf_vars,
          function(x) data.frame(ds2_1var(pdcy_phy_C_fam_trim, x),
                                Marker = x,
                                Subset = "C")),
    lapply(da_inf_vars,
          function(x) data.frame(ds2_1var(pdcy_phy_P_fam_trim, x),
                                Marker = x,
                                Subset = "P"))))

# Genus level comparisons:
gen_inf <- do.call("rbind",
  c(lapply(da_inf_vars,
            function(x) data.frame(ds2_1var(pdcy_phy_gen_trim, x),
                                    Marker = x,
                                    Subset = "all")),
    lapply(da_inf_vars,
          function(x) data.frame(ds2_1var_pdc(pdcy_phy_gen_trim, x),
                                Marker = x,
                                Subset = "pdc")),
    lapply(da_inf_vars,
          function(x) data.frame(ds2_1var(pdcy_phy_C_gen_trim, x),
                                Marker = x,
                                Subset = "C")),
    lapply(da_inf_vars,
          function(x) data.frame(ds2_1var(pdcy_phy_P_gen_trim, x),
                                Marker = x,
                                Subset = "P"))))

```

Collect and reorganize results:

```

# List taxa significant in any comparison
fam_inf_res_df <- subset(fam_inf, Family %in% unique(subset(fam_inf, padj < 0.05)$Family))
fam_inf_res_df$Taxon <- fam_inf_res_df$Family
fam_inf_res_df$Genus <- NA

gen_inf_res_df <- subset(gen_inf, Genus %in% unique(subset(gen_inf, padj < 0.05)$Genus))
gen_inf_res_df$Taxon <- gen_inf_res_df$Genus

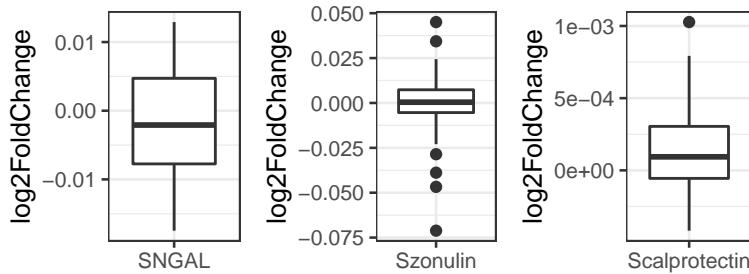

# Combined data frame
inf_res_df <- rbind(data.frame(fam_inf_res_df, Level = "Family"),
                      data.frame(gen_inf_res_df, Level = "Genus"))

# Reorganize for plotting
inf_res_df_m <- melt(inf_res_df)
inf_res_df_c <- dcast(inf_res_df_m, Marker + Taxon + Subset + Level ~ variable)
inf_res_df_c$pStar <- stars.pval(inf_res_df_c$padj)

```

Check the spreads of values for the log2 fold changes:

```
# Check the spreads of values for the log2 fc
do.call("grid.arrange",
  c(lapply(da_inf_vars, function(x)
    ggplot(subset(inf_res_df_c, Marker == x),
           aes(x = Marker, y = log2FoldChange)) +
      geom_boxplot() +
      xlab(NULL) +
      theme_bw(base_size = 10)), nrow = 1))
```

No major outliers. Export and plot the final results.

#### 3.4.2.1 Table S5B

```
# Rename the group levels
inf_res_df_c$Subset <- factor(inf_res_df_c$Subset, levels = c("all", "pdc", "C", "P"))
levels(inf_res_df_c$Subset) <- c("full data",
                                 "full data, corrected for PD/C and confounders",
                                 "control only", "PD only")
# Nicer names for the Marker variable
inf_res_df_c$Marker <- sub("^S", "Stool ", inf_res_df_c$Marker)

# Export full results
write.csv(inf_res_df_c, "Outputs/tableS5B.csv", row.names = FALSE)
```

grid.arrange(da_marker_plots)

```

### 3.4.2.3 Fig 4

Combine and export the plots for differentially abundant genera for SCFAs and markers:

```
# Blank panel for plotting
library("grid")
blankPanel <- grid.rect(gp = gpar(col = "white"), draw = FALSE)

da_plots <- arrangeGrob(da_scfa_plots,
  arrangeGrob(blankPanel, da_marker_plots, nrow = 1, widths = c(0.08, 1)),
  heights = c(length(unique(scfa_res_df_c_gen$Taxon)),
             length(unique(inf_res_df_c_gen$Taxon)))))

# Export combined figure
bitmap("Outputs/fig4_da_plots.tiff", width = 140, height = 210,
       units = "mm", res = 600)
grid.arrange(da_plots)
dev.off()

## pdf
## 2
```

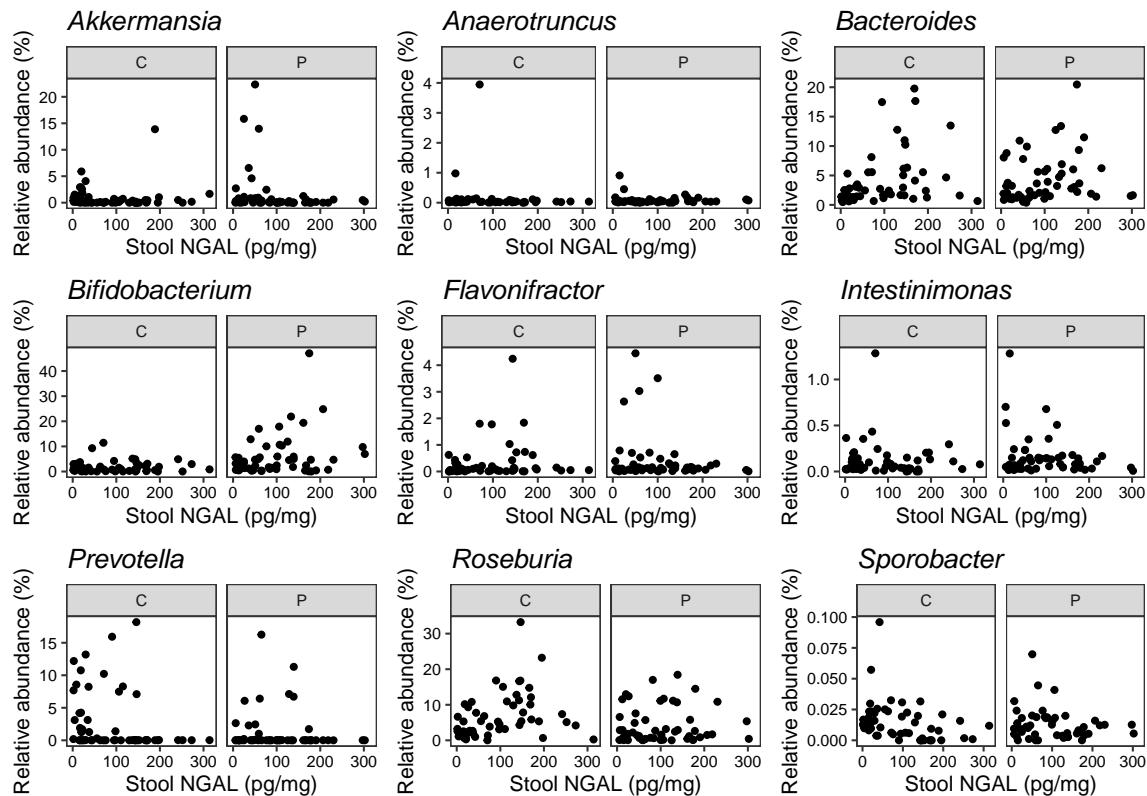

### 3.4.2.4 Fig S7

Separate plots for the most interesting taxa for each stool inflammatory marker:

#### NGAL

```
# List of significant taxa
ngal_sigs <- as.character(unique(
  subset(inf_res_df_c_gen, Marker == "Stool NGAL" & padj < 0.05)$Taxon))
```

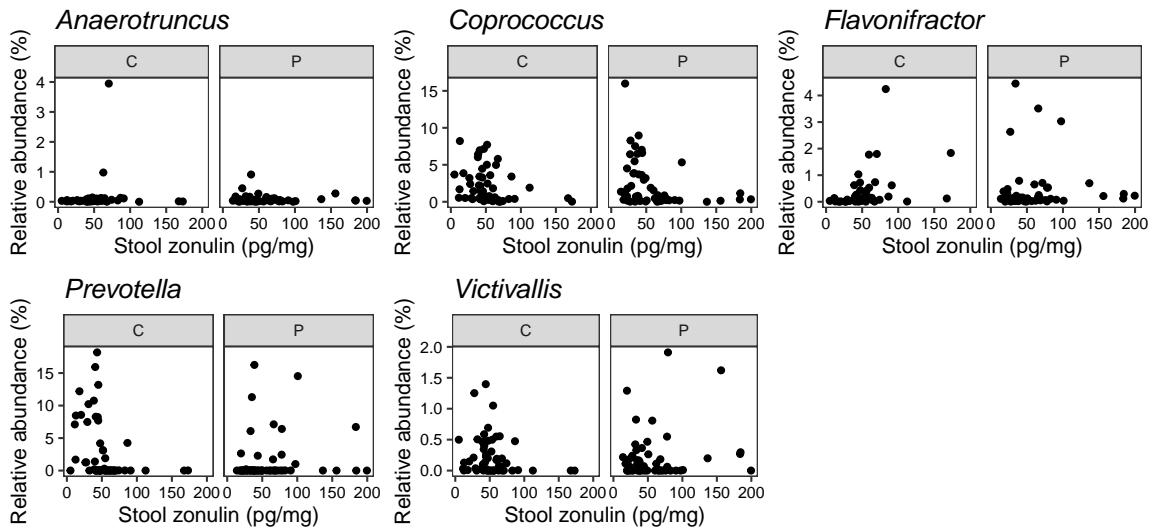

```
# Plot
ngal_da_scatters <- do.call(
  arrangeGrob, c(lapply(ngal_sigs, function(x)
    ra_scatter(ra_df, "SNGAL", x) +
    xlab("Stool NGAL (pg/mg)")), ncol = 3))
grid.arrange(ngal_da_scatters)
```

### Zonulin

```
zonu_sigs <- as.character(unique(
  subset(inf_res_df_c_gen, Marker == "Stool zonulin" & padj < 0.05)$Taxon))

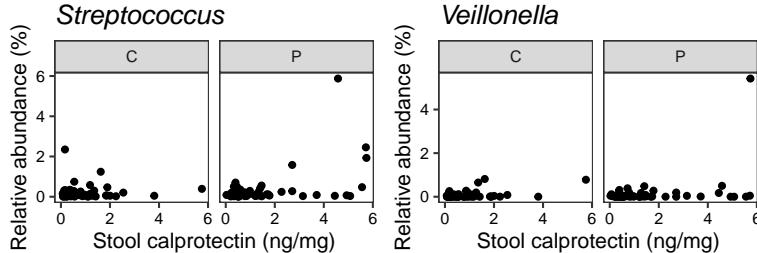

zonu_da_scatters <- do.call(
  arrangeGrob, c(lapply(zonu_sigs, function(x)
    ra_scatter(ra_df, "Szonulin", x) +
    xlab("Stool zonulin (pg/mg)")), ncol = 3))
grid.arrange(zonu_da_scatters)
```

### Calprotectin

```
calp_sigs <- as.character(unique(
  subset(inf_res_df_c_gen, Marker == "Stool calprotectin" & padj < 0.05)$Taxon))

calp_da_scatters <- do.call(
  arrangeGrob, c(lapply(calp_sigs, function(x)
    ra_scatter(ra_df, "Scalprotectin/1000", x) +
      xlab("Stool calprotectin (ng/mg)"), ncol = 3))
grid.arrange(calp_da_scatters)
```

Export the figures together:

```
library("grid")
# (repeated because for some reason knitr seems to forget it?)

pdf("Outputs/figS7_diffabund_scatters_markers.pdf",
  width = 7.5, height = 10)
grid.arrange(
  textGrob("A", x = unit(0.025, "npc"), y = unit(0.4, "npc"),
    gp = gpar(fontface = "bold", fontsize = 12)),
  ngal_da_scatters,
  textGrob("B", x = unit(0.025, "npc"), y = unit(0.4, "npc"),
    gp = gpar(fontface = "bold", fontsize = 12)),
  zonu_da_scatters,
  textGrob("C", x = unit(0.025, "npc"), y = unit(0.4, "npc"),
    gp = gpar(fontface = "bold", fontsize = 12)),
  calp_da_scatters,
  ncol = 1, heights = c(0.15, 3, 0.15, 2, 0.15, 1))
dev.off()
```

```
