**Figure S1. Fluidigm chip layout and N gene probes.** (A) The 192x24 Fluidigm chip can analyze 192 samples (from two 96-well microtiter plates) against 24 assays. In our experimental design, each sample was analyzed with 9 replicates each of the N1 and N2 (viral N gene) assays and 6 replicates of the RP (human gene) assay. (B) Schematics showing the locations of the PCR primers and Taqman probes for the N1 and N2 assays on the SARS-CoV-2 genome.

**Figure S2. Detection limit with RNA extraction step and the effect of carrier RNA.**

Workflow for the analysis of serially diluted Twist RNA only, Twist RNA with an RNA extraction step in presence of carrier RNA or Twist RNA with the direct addition of carrier RNA. Data show the mean  $\pm$  SD of valid Ct values from 18 replicates for each concentration (2 biological replicates with 9 technical replicates each).

**Figure S3. Linear regression of Ct values vs. copy number of serially diluted positive controls shows highly reproducible detection of SARS-CoV-2 across five orders of magnitude.** Plots of Ct values vs. copy number of serially diluted positive controls show a strong log linear relationship ranging from 5 to 50,000 copies/ $\mu\text{L}$  for both N1 and N2 assays (with preamplification). (A) synthetic RNAs (Twist RNA) and (B) SARS-CoV-2 plasmid. Data points show 18 replicates at each concentration.  $R^2$ , coefficient of variation.

**Figure S4. Comparison of detection performance between N1 and N2 assays.** (A) Correlation between Ct values of the N1 and N2 assays ( $R^2 = 0.86$ , Kendall's rank correlation). (B) Scatter plot of the differences in Ct values between the N1 and N2 assays ( $\Delta Ct (N1-N2)$ ) in the Pos\_Pos and Neg\_Pos samples.
