Supplement 1: Details of the model

The model consists of 66 differential equations. Men can either be susceptible (S), infected and unvaccinated (I) or infected and vaccinated (\hat{I}). In the notation below, the first subscript denotes the risk group k , where $k=\{1,2,3\}=\{\text{low, medium, high}\}$, the second subscript denotes whether the infection is symptomatic (0) or asymptomatic (1) and the third subscript denotes whether the infection is fully sensitive to antibiotics (0), has intermediate sensitivity MIC values (1), reduced sensitivity MIC values (2) or is resistant (3). Thus, $I_{k,10}$ indicates an unvaccinated man from risk class k who is asymptotically infected with the fully sensitive strain and $\hat{I}_{k,03}$ a vaccinated man from risk class k who is symptomatically infected with the resistant strain. The superscript “ w ” refers to the state in which first line treatment was not effective and people are waiting for their results from gonorrhoea culture and susceptibility testing and effective treatment (present for the reduced sensitivity and resistant strain).

All parameters are described in Table S1.1, and a graphical depiction of the model can be found in Figure S1.1.

Unvaccinated:

Susceptible:

$$\begin{aligned} \frac{dS_k}{dt} = & \mu N_k + (\theta - cov_k - \lambda_{k,0} - \lambda_{k,1} - \lambda_{k,2} - \lambda_{k,3} - \mu)S_k + \alpha_0(1 - \tau_\alpha)I_{k,00} + \alpha_0(1 - \tau_\alpha)I_{k,01} \\ & + \alpha_0(1 - \delta_2)(1 - \tau_\alpha)I_{k,02} + \alpha_{02}^w I_{k,02}^w + \alpha_0(1 - \delta_3)I_{k,03} + \alpha_{03}^w I_{k,03}^w \\ & + \alpha_{k,1}(1 - \tau_\alpha)I_{k,10} + \alpha_{k,1}(1 - \tau_\alpha)I_{k,11} + \alpha_{k,1}(1 - \delta_2)(1 - \tau_\alpha)I_{k,12} \\ & + \alpha_{k,1}(1 - \delta_3)I_{k,13} - \kappa S_k + \kappa N_k \sum_{j=1}^3 S_j \\ & + \gamma(I_{k,00} + I_{k,01} + I_{k,02} + I_{k,02}^w + I_{k,03} + I_{k,03}^w + I_{k,10} + I_{k,11} + I_{k,12} + I_{k,13}) \end{aligned}$$

Symptomatically infected:

$$\frac{dI_{k,00}}{dt} = \zeta \lambda_{k,0} S_k - (\gamma + \mu)I_{k,00} + \theta \hat{I}_{k,00} - (\alpha_0 + \tau)I_{k,00} - \kappa I_{k,00} + \kappa N_k \sum_{j=1}^3 I_{j,00}$$

$$\frac{dI_{k,01}}{dt} = \zeta\lambda_{k,1}S_k - (\gamma + \mu)I_{k,01} + \theta\hat{I}_{k,01} - (\alpha_0 + \tau)I_{k,01} + (\alpha_0\tau_\alpha + \tau)I_{k,00} - \kappa I_{k,01} + \kappa N_k \sum_{j=1}^3 I_{j,01}$$

$$\frac{dI_{k,02}}{dt} = \zeta\lambda_{k,2}S_k - (\gamma + \mu)I_{k,02} + \theta\hat{I}_{k,02} - (\alpha_0 + \tau)I_{k,02} + (\alpha_0\tau_\alpha + \tau)I_{k,01} - \kappa I_{k,02} + \kappa N_k \sum_{j=1}^3 I_{j,02}$$

$$\frac{dI_{k,02}^w}{dt} = \alpha_0\delta_2(1 - \tau_\alpha)I_{k,02} - (\gamma + \mu)I_{k,02}^w + \theta\hat{I}_{k,02}^w - \alpha_{02}^w I_{k,02}^w - \kappa I_{k,02}^w + \kappa N_k \sum_{j=1}^3 I_{j,02}^w$$

$$\frac{dI_{k,03}}{dt} = \zeta\lambda_{k,3}S_k - (\gamma + \mu)I_{k,03} + \theta\hat{I}_{k,03} - \alpha_0 I_{k,03} + \tau I_{k,02} - \kappa I_{k,03} + \kappa N_k \sum_{j=1}^3 I_{j,03}$$

$$\frac{dI_{k,03}^w}{dt} = \alpha_0\delta_3 I_{k,03}^w + \alpha_0\tau_\alpha I_{k,02} - (\gamma + \mu)I_{k,03}^w + \theta\hat{I}_{k,03}^w - \alpha_{03}^w I_{k,03}^w - \kappa I_{k,03}^w + \kappa N_k \sum_{j=1}^3 I_{j,03}^w$$

Asymptotically infected:

$$\frac{dI_{k,10}}{dt} = (1 - \zeta)\lambda_{k,0}S_k - (\gamma + \mu)I_{k,10} + \theta\hat{I}_{k,10} - (\alpha_{k,1} + \tau)I_{k,10} - \kappa I_{k,10} + \kappa N_k \sum_{j=1}^3 I_{j,10}$$

$$\begin{aligned} \frac{dI_{k,11}}{dt} &= (1 - \zeta)\lambda_{k,1}S_k - (\gamma + \mu)I_{k,11} + \theta\hat{I}_{k,11} - (\alpha_{k,1} + \tau)I_{k,11} + (\alpha_{k,1}\tau_\alpha + \tau)I_{k,10} - \kappa I_{k,11} \\ &\quad + \kappa N_k \sum_{j=1}^3 I_{j,11} \end{aligned}$$

$$\begin{aligned} \frac{dI_{k,12}}{dt} &= (1 - \zeta)\lambda_{k,2}S_k - (\gamma + \mu)I_{k,12} + \theta\hat{I}_{k,12} - (\alpha_{k,1}(1 - \delta_2) + \tau)I_{k,12} + (\alpha_{k,1}\tau_\alpha + \tau)I_{k,11} - \kappa I_{k,12} \\ &\quad + \kappa N_k \sum_{j=1}^3 I_{j,12} \end{aligned}$$

$$\begin{aligned} \frac{dI_{k,13}}{dt} &= (1 - \zeta)\lambda_{k,3}S_k - (\gamma + \mu)I_{k,13} + \theta\hat{I}_{k,13} - \alpha_{k,1}(1 - \delta_3)I_{k,13} + (\alpha_{k,1}(1 - \delta_2)\tau_\alpha + \tau)I_{k,12} \\ &\quad - \kappa I_{k,13} + \kappa N_k \sum_{j=1}^3 I_{j,13} \end{aligned}$$

Vaccinated:

Susceptible:

$$\begin{aligned}
\frac{d\hat{S}_k}{dt} = & (cov_k - \theta - \hat{\lambda}_{k,0} - \hat{\lambda}_{k,1} - \hat{\lambda}_{k,2} - \hat{\lambda}_{k,3} - \mu)\hat{S}_k + \alpha_0(1 - \tau_\alpha)\hat{I}_{k,00} + \alpha_0(1 - \tau_\alpha)\hat{I}_{k,01} \\

& + \kappa N_k \sum_{j=1}^3 \hat{I}_{j,12}
\end{aligned}$$

$$\frac{d\hat{I}_{k,13}}{dt} = (1 - \zeta)\hat{\lambda}_{k,3}\hat{S}_k - (\gamma f_d + \mu + \theta)\hat{I}_{k,13} - \alpha_{k,1}(1 - \delta_3)\hat{I}_{k,13} + \tau\hat{I}_{k,12} - \kappa\hat{I}_{k,13} + \kappa N_k \sum_{j=1}^3 \hat{I}_{j,13}$$

The force of infection (per year) λ_{ki} for unvaccinated and $\hat{\lambda}_{ki}$ for vaccinated per risk class $k=1,2,3$, and infection strain $i=0,1,2,3$ (0=fully sensitive strain, 1= intermediate sensitivity, 2=reduced sensitivity, 3=resistant) is given by:

$$\lambda_{k,0} = c_k \sum_{j=1}^3 m_{kj} \left(\beta \frac{I_{j,00} + I_{j,10}}{N_j} + \beta f_t \frac{\hat{I}_{j,00} + \hat{I}_{j,10}}{N_j} \right)$$

$$\lambda_{k,1} = c_k \sum_{j=1}^3 m_{kj} \left(\beta \psi \frac{I_{j,01} + I_{j,11}}{N_j} + \beta \psi f_t \frac{\hat{I}_{j,01} + \hat{I}_{j,11}}{N_j} \right)$$

$$\lambda_{k,i} = c_k \sum_{j=1}^3 m_{kj} \left(\beta \psi \frac{I_{j,0i} + I_{j,1i}^w + I_{j,1i}}{N_j} + \beta \psi f_t \frac{\hat{I}_{j,0i} + \hat{I}_{j,1i}^w + \hat{I}_{j,1i}}{N_j} \right), i = 2,3$$

$$\hat{\lambda}_{k,0} = c_k \sum_{j=1}^3 m_{kj} \left(\beta f_s \frac{I_{j,00} + I_{j,10}}{N_j} + \beta f_t f_s \frac{\hat{I}_{j,00} + \hat{I}_{j,10}}{N_j} \right)$$

$$\hat{\lambda}_{k,1} = c_k \sum_{j=1}^3 m_{kj} \left(\beta \psi f_s \frac{I_{j,01} + I_{j,11}}{N_j} + \beta \psi f_t f_s \frac{\hat{I}_{j,01} + \hat{I}_{j,11}}{N_j} \right)$$

$$\hat{\lambda}_{k,i} = c_k \sum_{j=1}^3 m_{kj} \left(\beta \psi f_s \frac{I_{j,0i} + I_{j,1i}^w + I_{j,1i}}{N_j} + \beta \psi f_t f_s \frac{\hat{I}_{j,0i} + \hat{I}_{j,1i}^w + \hat{I}_{j,1i}}{N_j} \right), i = 2,3$$

The force of infection takes into account the fitness costs of the resistant strain, and the reductions in transmissibility or susceptibility when vaccinated. The force of infection depends on the partner change rates and mixing between MSM. Mixing is described by a matrix with the elements m_{ij}

$$m_{ij} = \omega \frac{c_j N_j}{\sum_{p=1}^3 c_p N_p} + (1 - \omega) \kappa_{ij}$$

Where $\kappa_{ij} = 1$ if $i = j$ and $\kappa_{ij} = 0$ otherwise.

The model is programmed in Wolfram Mathematica 11. The code is available upon request.

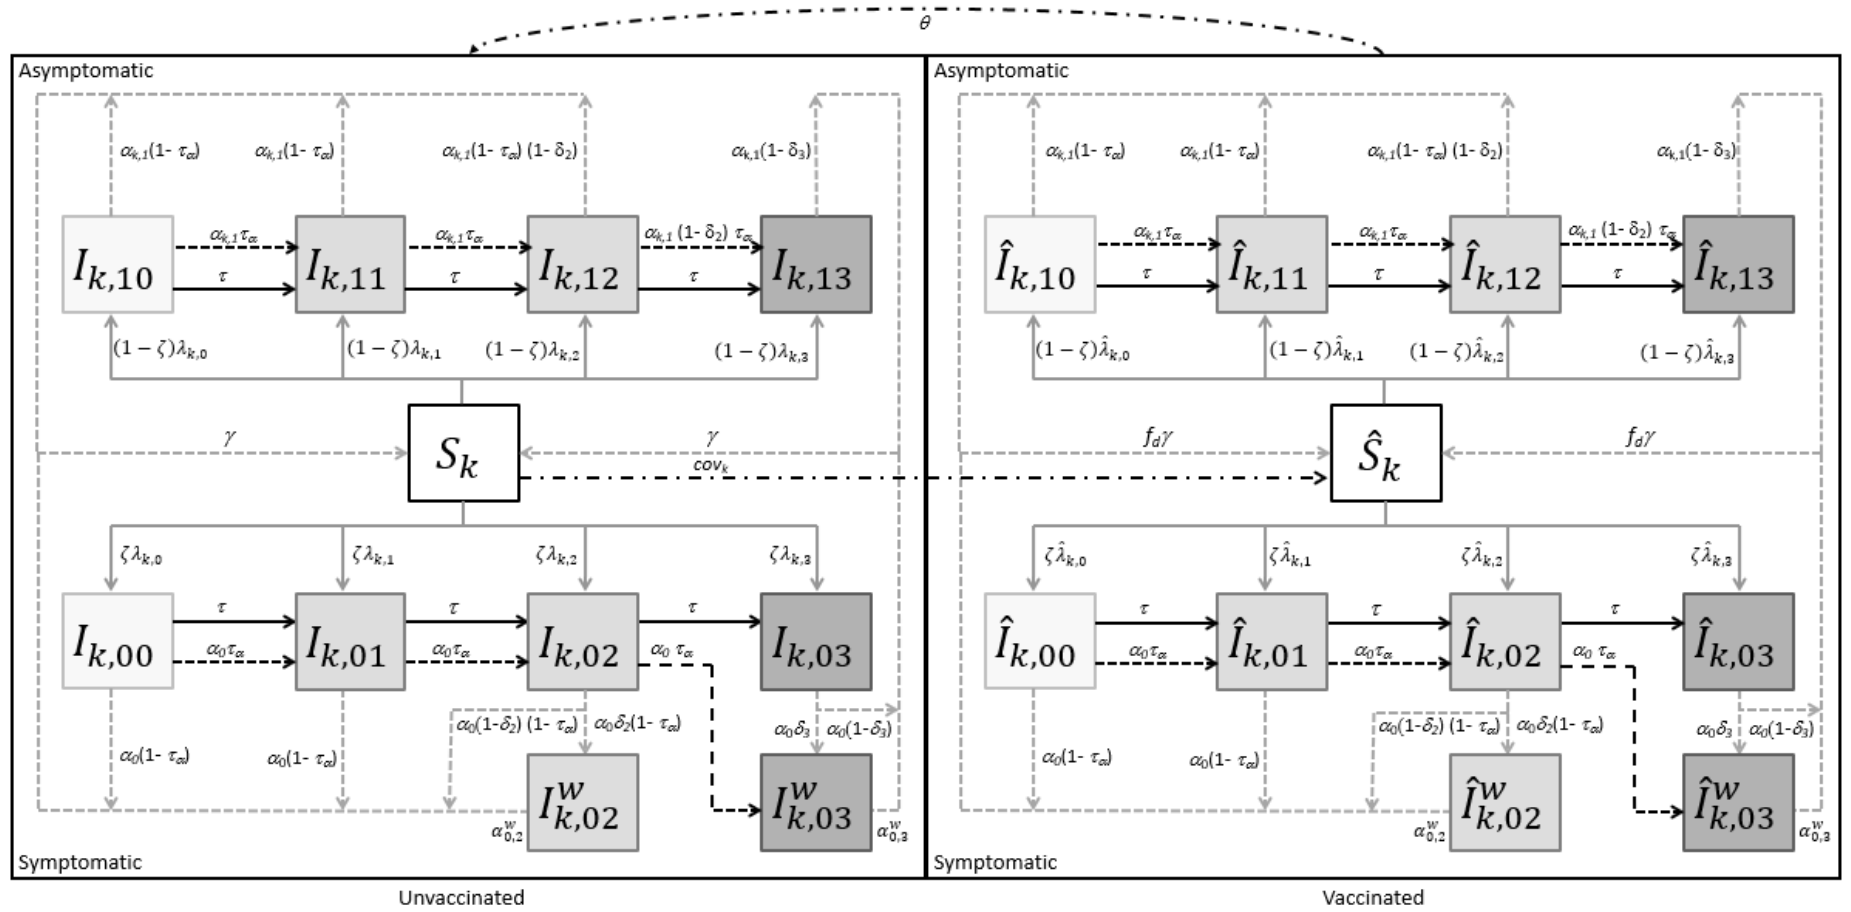

Figure S1.1. Schematic overview of the model in asymptotically (top) and symptomatically (bottom) infected MSM who are unvaccinated (left) or vaccinated (right) and in risk class k .

Table S1.1. Overview of all parameters.

Symbol	Explanation	Baseline value [Min-Max range]*
<i>Population</i>		
$1/\mu$	Duration of sexual active life (years)	45
N_k	Proportion (%) sexual activity class k (low, medium, high)	(0.715, 0.261, 0.024)
<i>Infection</i>		
$1/\gamma$	Duration of infection (months)	4.5
ζ	Proportion of infections being symptomatic	0.3
β	Transmission probability per sex act	0.37 [0.36 – 0.40]
$1-\psi$	Fitness cost (%)	0
τ	Rate of mutant strain selection during the infectious period resulting in strain with higher MIC values	0.00413 [0.0038 – 0.0053]**
τ_α	Rate of mutant strain selection upon ceftriaxone treatment resulting in strain with higher MIC values	0.00318 [0.0026 – 0.0032]**
<i>Sexual behaviour</i>		
ω	Mixing (0: assortative 1: proportionate)	0.79 [0.74 – 1.00]
κ	Redistribution rate to same or other activity class (per year)	0.2
c_k	Contact rate (number of partners or CAI acts per year) for sexual activity class k (low, medium, high)	(6.56, 12.77, 36.12)
<i>Testing and treatment</i>		
$1/\alpha_0$	Average time from infection to treatment symptomatics (days)	14
δ_2	Treatment failure among people infected with reduced sensitivity MIC levels strain (%)	0.5
δ_3	Treatment failure among people infected with resistant MIC levels strain (%)	20
$1/\alpha_{0,2}^w$	Average time between treatment failure and successful treatment among symptomatic infected men with the reduced sensitivity strain (days)	21
$1/\alpha_{0,3}^w$	Average time between treatment failure and successful treatment among symptomatic infected men with resistant strain (days)	31
$\alpha_{k,1}$	Testing rate (per year) asymptomatic infected individuals in activity class k (low, medium, high)	(0.18 [0.05 – 0.20], 0.25 [0.20 – 0.50],

1.48 [0.50 – 1.49])

Vaccination

$1/\theta$	Duration of vaccine protection (years)	2
$1/f_d$	Factor influencing duration of infection when vaccinated	NA
$1-f_t$	Factor determining the reduction in transmission when infected and vaccinated	NA
$1-f_s$	Factor determining the reduction in susceptibility when vaccinated	0.3
cov_k	Vaccination uptake sexual activity class k (low, medium, high)	(0, 0, 0.4)

NA: not applicable in baseline analyses. These are used in the uncertainty analyses.

* The minimum and maximum values of the used 343 parameter sets (see supplement 3).

** In the uncertainty analyses, one rate of developing a mutation resulting in strain with higher MIC values was set to zero, and the other one was fitted to the MIC curve and vice versa.

Supplement 2: Gonorrhoea positivity and behavioral parameters

The partner change rates and percentages of people in each of the activity classes are informed by the Amsterdam Cohort Studies on HIV and AIDS (ACS) and are based on [1]. In short, the ACS is a population based open cohort study on the epidemiology, psychosocial determinants, course of infection and pathogenesis of HIV. It is an open cohort, and once enrolled, MSM receive bi-annual STI and HIV testing and fill out a questionnaire [2]. To define the sexual activity classes in [1], data was used from 803 HIV-negative MSM who participated in the ACS between May 2007 and January 2017, which resulted in a total of 8,198 visits. A risk score was developed incorporating behavioral factors predictive of HIV seroconversion (including number of anal intercourse partners, condom use and group sex). These factors are also well known factors of acquiring a gonorrhoea infection. Based on this risk score, we defined three levels of sexual activity (low, medium and high), which determined the group size of each class [1]. The partner change rates for each sexual activity class was based on the average number of casual partners with whom men reported having condomless anal intercourse or oral intercourse in the last half year. This was multiplied by 1.5 [1] to obtain number of partners in the last year per risk group.

We also used the average percentage of people with a gonorrhea diagnosis (at any anatomical location, including pharyngeal, urogenital and anorectal location) in the past six months in each sexual activity class (Table S3.2). Between October 2008 and January 2017, gonorrhea was tested in the ACS at 6,963 visits. Self-collected anal swab and urine sample were tested using nucleic acid amplification tests (NAATs; Aptima combo 2, Hologic, Marlborough, MA, USA). This is used as prevalence to fit the unknown parameters of the model to (see Supplement 3).

Supplement 3: Fitting procedure

Gonorrhoea prevalence

We fitted the unknown parameters to the risk-group specific prevalence as reported in the ACS. We defined uniform probability distributions for all unknown parameters (Table S3.1)

Table S3.1. The distributions for each parameter used in the fitting.

Parameter		Distribution
ω	Mixing	U[0,1]
$\alpha_{L,1}$	Testing rate asymptomatic infected individuals low risk	U[0.05, 0.2]
$\alpha_{M,1}$	Testing rate asymptomatic infected individuals medium risk	U[0.2, 0.5]
$\alpha_{H,1}$	Testing rate asymptomatic infected individuals high risk	U[0.5, 1.5]

The distributions were then sampled 4900 times using Latin hypercube sampling. For each parameter set, the transmission probability (β) was fitted to the risk group specific steady state prevalence by minimizing the sum of the squared residuals. Of the 4900 parameter sets, 3863 (79%) resulted in a beta that was between 0 and 1. Of those, we selected the first 500 parameter set that resulted in the lowest sum of the squared residuals. These 500 parameters were then used to fit the rate of developing a mutation resulting in strain with higher MIC values.

AMR – baseline analyses

To determine the two rates of developing a mutation resulting in strain with higher MIC values (i.e. during the infectious period and upon treatment), the model was then run into steady state with the fully sensitive strain only after which treatment with ceftriaxone was introduced in 2006 [3]. The mutation probabilities were fitted to the MIC curves for ceftriaxone from the Dutch GRAS surveillance for the years 2015 – 2019 [4]. This was also done by minimizing the sum of the squared residuals. Of the 500 parameter sets, 343 (68.6%) resulted in a good fit and could be used.

The parameter set that provided the best fit (lowest sum of squared residuals) was used as baseline values and the 343 parameter sets provide the input for the 95% credible intervals in all analyses.

Table S3.2. Prevalence from the data and the model.

Activity class	Data	Model
	% (95% confidence interval)	Baseline (95% credible interval)
Overall	3.0% (2.6% – 3.5%)	3.4% (3.2% – 3.8%)
Low	1.7% (1.4% – 2.1%)	2.5% (2.4% – 3.0%)
Medium	5.5% (4.5% – 6.6%)	5.0% (4.5% – 5.4%)
High	12.4% (8.0% – 18.2%)	12.5% (12.1% – 12.7%)

AMR – uncertainty analyses

We performed an uncertainty analyses by fitting the model to the MIC curve by assuming that new strain development could only happen upon treatment. This was also done by minimizing the sum of the squared residuals. Of the 500 parameter sets, 190 (38%) resulted in a good fit and could be used. The median resulting rate of developing a mutation resulting in strain with higher MIC values upon treatment was 0.012 (min: 0.011, max: 0.023).

For the uncertainty analyses assuming that new strain development could only happen upon treatment, all 500 parameter sets could be used. The median resulting rate of developing a mutation resulting in strain with higher MIC values during infectious period was 0.0063 (min: 0.0063, max: 0.0063).

The uncertainty analyses assuming that the new strains were less fit (i.e. 5% lower transmission probability) and both forms of new strain development (upon treatment and during infectious period) were more difficult to fit: only 4 of 500 parameter sets could be used (all others resulted in a negative rate). The median rate of developing a mutation resulting in strain with higher MIC values upon treatment was 0.0065 (min: 0.0060, max: 0.0066) and rate of developing a mutation resulting in strain with higher MIC values during infectious period was 0.0099 (min: 0.0098, max: 0.0104).

Supplement 4: Uncertainty analyses

Table S4.1 Effect on prevalence and relative reduction of prevalence (in 2050) of a partially protective vaccine that reduces **transmissibility** of *N. gonorrhoeae* for a vaccine with vaccine effectiveness(VE) of 30% and different vaccination uptake in high activity MSM or a vaccination uptake of 40% and different VE.

		Overall		Non-resistant strains		AMR
		Prevalence	Relative reduction	Prevalence	Relative reduction	Prevalence
