#### 1. Sample details

**Supplementary Table 1: Demographic information of patients.** Samples were taken with consent from >18 years old patients visiting STI clinics with genital discharge or fluid (watery, pus). CSW- commercial sex work, NG- *N. gonorrhoeae*, NM- *N. meningitidis*, MO- *Moraxella osloensis*, HIV- Human immunodeficiency virus. Only NG genomes were analysed further, genomes marked with \* were found to have a lot of gaps and were not considered. R – Radio, B- Barazas, T- Television, F – Friends, N- Newspaper, O- Other sources.

## 2. Determining antibiotic susceptibility

1. E-test strips were allowed to come to room temperature before opening the container.
2. Using the Vitek colourimeter or standard turbidity tube, we prepared a suspension of the test organism in sterile Muller Hinton broth, the organism was inoculated until it reached sufficient turbidity equivalent to 0.5 McFarland standards.
3. Dacron swab was used to inoculate from the pure culture onto an agar plate, streaking in 3 directions i.e. over the entire agar surface.
4. Incubation was carried out at 37°C and CO<sub>2</sub> concentration (5%) and interpreted as per the instruction on the insert.

MIC's above a documented specific level for each antibiotic as per the CLSI guidelines constitute "resistance" of a strain to that antibiotic while MIC's above the normal MIC level but below the critical level for the definition of resistance constitute strains with decreased susceptibility to a given antibiotic.

**Supplementary Table 2: MIC reference used in the study.** MICs (µg/ml) for the interpretation of susceptibility of strains of *N. gonorrhoeae* to selected antimicrobial agents, as recommended by CLSI for interpretation of resistance.

| Antimicrobial agents | Susceptible (S) | Intermediate (I) | Resistant (R) |
|----------------------|-----------------|------------------|---------------|
| Ceftriaxone          | ≤0.25 µg/ml     | .                | >0.25 µg/ml   |

|               |                            |                             |                            |
|---------------|----------------------------|-----------------------------|----------------------------|
| Cefixime      | $\leq 0.25 \mu\text{g/ml}$ | .                           | $> 0.25 \mu\text{g/ml}$    |
| Ciprofloxacin | $\leq 0.06 \mu\text{g/ml}$ | $0.12 - 0.5 \mu\text{g/ml}$ | $> 1 \mu\text{g/ml}$       |
| Spectinomycin | $\leq 32 \mu\text{g/ml}$   | $64 \mu\text{g/ml}$         | $> 128 \mu\text{g/ml}$     |
| Erythromycin  | $\leq 0.25 \mu\text{g/ml}$ | $0.38 - 1.0 \mu\text{g/ml}$ | $1.5 - 4.0 \mu\text{g/ml}$ |
| Azithromycin  | $\leq 0.25 \mu\text{g/ml}$ | $0.5 \mu\text{g/ml}$        | $> 1.0 \mu\text{g/ml}$     |
| Tetracycline  | $\leq 0.25 \mu\text{g/ml}$ | $0.5 - 1.0 \mu\text{g/ml}$  | $> 2 \mu\text{g/ml}$       |
| Penicillin    | $\leq 0.06 \mu\text{g/ml}$ | $0.12 - 1.0 \mu\text{g/ml}$ | $> 2 \mu\text{g/ml}$       |
| Gentamycin    | $\leq 4 \mu\text{g/ml}$    | $8 - 16 \mu\text{g/ml}$     | $> 32 \mu\text{g/ml}$      |

### 3. Genome assembly and read statistics

**Supplementary Figure 1: Pipeline for *de novo* assembly.** The workflow followed for *de novo* genome assembly, error correction and genome polishing using Canu and Minimap-Miniasm, has been depicted in the figure.

**Supplementary Figure 2: Mappability of the reads to the reference genome.** The number of reads vs depth and genome coverage for the nine strains has been plotted. We observe that the increase in reads/coverage does not necessarily indicate an increase in genome coverage.

#### 4. Comparison of assembly statistics for assemblies obtained using different methods

**Supplementary Table 3a: Assembly statistics for the reference-based assembly.** Bwa-mem was used for the assembly followed by samtools and bcftools for deriving the consensus from the assembly.

| Strain ids.         | 3                | 12               | 18                | 57               | 61                | 100A             | 200              | 274               | 285               | 298               |

## 7. Mutations resulting in AMR

Multiple mutations have been reported in many genes conferring resistance to different classes of antibiotics in *N. gonorrhoeae*. A brief overview of the mutations in the genes and their possible modes of action is provided in this section.

Quinolones (eg.Ciprofloxacin) affect bacterial DNA replication by interacting with proteins like DNA gyrase (GyrA) and topoisomerase IV (ParC). Mutations in these proteins in the quinolone resistance determining region (QRDR), which alter the quinolone binding site, have been shown to cause resistance<sup>1</sup>. The β-Lactam antibiotics, penicillins and cephalosporins, inhibit bacterial cell wall synthesis by binding to transpeptidase enzymes (penicillin-binding proteins or PBPs). TEM-1 gene-containing plasmids encode a TEM-1-type β-lactamase which hydrolyzes the β-lactam ring and renders the penicillin inactive<sup>2</sup>. Mutations in genes encoding penicillin-binding proteins (*penA*, *ponA1*, *penC/pilQ*), *mtrR* (repressor of MtrCDE efflux pump) and the porin, *porB1b* result in resistance to β-lactam antimicrobials<sup>1</sup>. Mutations in *mtrR*

promoter result in overexpression of MtrCDE efflux pump, causing multi-drug resistance; while porin mutations cause a slightly lower influx of antibiotics in the cell<sup>3</sup>.

Tetracyclines inhibit protein synthesis by binding to the 30S ribosomal subunit. Plasmid-encoded *tet(M)* resembles elongation factor G (EF-G) and binds to the ribosomes causing the release of the tetracycline molecule. Mutations in ribosomal binding protein S10, encoded by *rpsJ* (V57M) results in tetracycline resistance, in strains with mutations in *penB* and *mtrR*<sup>1</sup>. Spectinomycin inhibits translation by binding to the 30S ribosomal subunit, specifically to the 16S rRNA and 30S ribosomal protein S5p (*rpsE*). Mutations in these two genes result in resistance to spectinomycin. Macrolides inhibit protein synthesis by binding to the 50S ribosomal subunit, specifically 23S rRNA. Macrolide resistance results from mutations in 23S rRNA or by the acquisition of conjugative transposon encoded proteins which cause either modification of 23S rRNA by rRNA methylase (*erm* genes) blocking macrolide interaction or overexpression of efflux pump system (*mef* pump)<sup>4</sup>.

Sulfonamides inhibit the synthesis of folic acid, by targeting the dihydropteroate synthase. Mutations in this antibiotic target, *folP*, increases sulphonamide MIC<sup>5</sup>. Mutations in the *mtrR* DNA-binding domain affects repression resulting in overexpression of the MtrCDE efflux pump system leading to multi-drug resistance. Promoter mutations in the genes coding for efflux pumps NorM and MacAB cause resistance to fluoroquinolones and macrolides, respectively<sup>1</sup>.

**Supplementary Table 6a: List of the mutations identified through literature.** The novel mutations observed in our study have been indicated in bold.

| Antibiotic class | Reference                                                              | Gene        | Mutation    | Residue in the reference genome |

## 8. Investigation of the structural basis for antibiotic resistance mutations

Of all the mutations reported in the literature, in the genes listed above, our strains had mutations in only a few genes. Homology modelling of a few proteins was carried out to understand the basis of drug resistance, which has been discussed below.

**Supplementary Table 7: Template details of homology modelling for the proteins with mutations resulting in AMR.**

| <b>Protein and gene name</b>                           | <b>PDB id</b> | <b>Resolution</b> | <b>PDB details</b>                                            | <b>Reference organism</b>      | <b>% identity</b> |

## 9. Basis of drug resistance

Ribosomal protein S10 (*rpsJ*)- V57M mutation is associated with resistance to tetracycline. From studies on the structure of the 30S ribosomal subunit from *Thermus thermophilus* (PDB id: 1HNW)<sup>13</sup>, this residue was seen to be close to the tetracycline-binding site in RpsJ. The presence of hydrophobic side chains at this site is thought to alter the structure and reduce the binding affinity of tetracycline<sup>14</sup>.

Ribosomal protein L4p (*rplD*)- G70 residue is predicted to make contacts with azithromycin bound to the 50S ribosome from studies in *Thermus thermophilus*<sup>15</sup>.

*penA*-<sup>16</sup>. The D345a residue is involved in a hydrogen bond network with catalytic serine residue, which may prevent the acylation of R1 subunit of penicillin, resulting in resistance. The mutation F504L occurs in the  $\beta 3$ – $\beta 4$  loop. This loop is thought to be important for the flexibility and resistance to beta-lactams, as inferred from studies in *Streptococcus pneumoniae*<sup>17,18</sup>.

*mtrR*- The MtrR protein from *N. gonorrhoeae* has been crystallised (PDB id: 6OF0)<sup>19</sup>. The mutations A39T and H105 are observed in the  $\alpha 2$  helix which is a part of the DNA binding domain and  $\alpha 6$ , respectively, which is closer to the DNA binding region, in the wild-type protein structure. A39T mutation is thought to decrease the affinity of MtrR for *mtrCDE* promoter region, leading to resistance<sup>19</sup>.

*porB1b*- Structure of outer membrane porin F from *E. coli* in complex with ampicillin (PDB id: 4GCP) was used as the template for homology modelling of PorB1b protein from reference strain (G120, A121, N122) and our sequenced strain 57 (D120, G121 and D122). Gly120 and Asp121 and Asn122 mutations confer intermediate resistance to penicillin and tetracycline and are located in the loop3 region which forms the pore constriction zone<sup>20</sup>. The mutated residues are shown in Figures S1a-c. These side chains could be lining a substrate translocation pathway, consistent with observations that mutations decrease antibiotic permeability<sup>1</sup>.

*ponA1* has only one reported mutation in *N. gonorrhoeae*, L421P, which occurs about 40 residues to the upstream of catalytic residue S460 and confers resistance to penicillin and extended-spectrum cephalosporins<sup>18</sup>. We modelled the structure of wild-type and mutant *ponA1* from strain 3 using the template, *Acinetobacter baumannii* PBP1a in complex with penicillin G (PDB id: 3UDI)<sup>21</sup>. The homology model revealed that the mutation occurs in the C-terminal end of the ODD (outer-membrane PBP1A docking domain), which acts as a linker between the transpeptidase domain and glycosyltransferase domain (Figures S2a-c)<sup>21</sup>. The domain has been suggested to serve as a structural intermediary between the two domains<sup>17</sup> and in the formation of a hydrophobic patch to selectively regulate substrate entry into the catalytic pocket<sup>22</sup>, based on studies in other bacteria.

## 10. Phylogenetic analysis with strains across the world

**Supplementary Table 8: Details for strains used in phylogeny analysis.** The analysis was carried out using the genome comparator module of BIGSdb, and details like country and antibiotic resistance were derived from PubMLST using a keyword search for strain ids. Colour code: Dark yellow with red text- Resistant, Cream with green text- Intermediate.

| id    | isolate  | country | continent     | penicillin | ceftriaxone | ciprofloxacin | tetracycline | cefixime | azithromycin | Doxycycline | spectinomycin |

## Figures

**Supplementary Figure 3:** The modelled structure of the porB1b complex with ampicillin (a). A close-up of the antibiotic-binding pocket showing ampicillin (red) and the residues G120, A121, N122 in reference strain structure (b) and in the triple mutant D120, G121 and D122 (magenta) (c). The polar contacts for the antibiotic are shown as yellow dashes.

**Supplementary Figure 4:** The modelled structure of the *ponA1* complex with penicillin (a). A close-up of the antibiotic-binding pocket showing penicillin G (red), L421 (magenta) in wild-

type structure (b) and L421P mutant (magenta) (c). The polar contacts for the antibiotic are shown as yellow dashes.
