Supplementary Information 1:

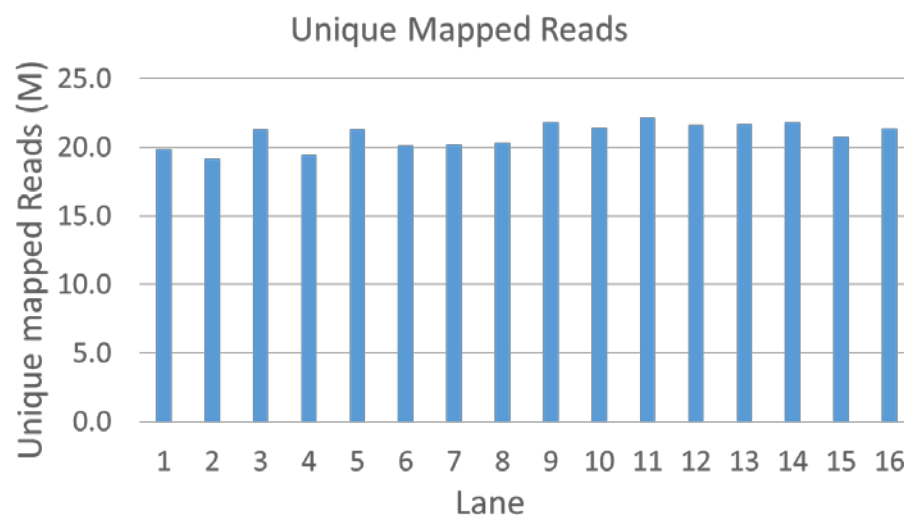

Each terminator shows different fluorescence intensity according to dye-labeled-nucleotides' structure and optical property. In sequencing, the average intensity and background show consistently fluctuations as the terminator combinations switch every cycle. On the other hand, the SNR shows similar pattern and slightly increase in later cycle. Those phenomenon is the results of less background scattering caused by decreasing fluorescence signal density over time.

Supplementary Figure 1. (A) Normalized fluorescence intensity and background at 552nm and 664nm change in 70 cycle sequencing. (B) SNR in 70 cycles sequencing.

Supplementary Information 2:

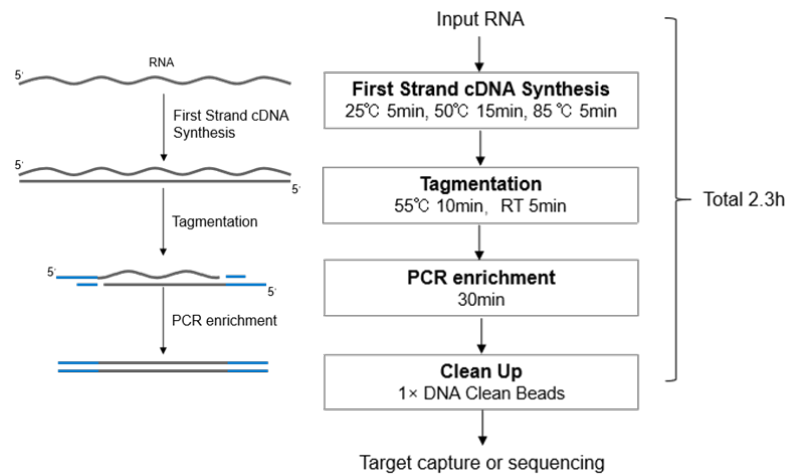

We hybridized and sequenced Phix 174 in a 16-lane flow cell using 72 cycles. The unique reads of each lane have been shown below (**Supplementary Figure 2**):

Supplementary Figure 2. Unique mapped reads of phix174 samples in 16 lanes.

Supplementary Information 3:

Libraries of RNA samples from throat swabs are prepared using Tn5 transposome methods (**Supplementary Figure 3**). After reverse transcription, Tn5 transposome can randomly bind RNA/DNA heteroduplex and add sequencing adaptors. The complete libraries are obtained by PCR.

Supplementary Figure 3. Library preparation process for SARS-CoV-2 sample using transposase method.

Supplementary Information 4:

We used Sanger sequencing to confirm detected mutations on GenoCare™ 1600. The results are shown below:
